Those who have had experience in the treatment of the ordinary bromide papers will require very few directions or warnings in regard to the use of Alpha paper. An exposure somewhat more protracted is required than with bromide papers; the same cleanliness in the manipulations must be observed; iron development, or, if very careful clearing is attended to, alkaline development may be employed. Next, an immediate application of acid and alum clearing solution, followed by washing, and, if thought necessary, toning in a gold or gold and platinum bath, then the usual fixation, varied in length of time in certain cases, according to the colour, warm or cold, required; and, finally, a thorough washing in several changes of water.

In regard to developers, the formula given with the paper works exceedingly well, but as oxalate of potash and sulphate of iron are generally kept in saturated solutions, directions should be given simply to make the required formula from these stock solutions instead of putting each operator to the trouble of making the necessary calculations for himself. For the sake of any who have their oxalate and iron in saturated solutions and may wish to be spared the trouble of mixing a special developer, the following directions may be given:—

- | | | |
|----|---|------------------------|
| | { Saturated solution oxalate of potash | 2 ounces. |
| 1. | { A ten per cent. solution of bromide of ammonium | 60 to 180 drops. |
| | { Water | $\frac{1}{2}$ ounce. |
| | { Saturated solution sulphate of iron | $\frac{1}{2}$ ounce. |
| 2. | { Citric acid | 10 grains. |
| | { Water | $3\frac{1}{2}$ ounces. |

For development, take equal parts of each; the iron *must* be added to the oxalate. If larger quantities are required, of course multiples of the above must be taken. The bromide must be varied to suit circumstances. The citric acid can be put in by guesswork.

This developer is weak and well restrained, and the object of this is to make more certain of producing a warm colour in development, and thus to avoid the somewhat unpleasant greenish colour apparently given by some negatives under a short exposure and stronger development.

A clearing solution may be made by taking from ten to twelve ounces saturated solution of alum, adding ten ounces water and a quarter ounce of citric acid.

After washing, a toning bath, if one be required, may be used. That recommended in the directions with the paper, any acetate bath, or a bicarbonate, are found to work equally well, but more chloride of gold will be found to be required than in toning ordinary silver paper. But in many cases toning can be dispensed with.

The fixing bath should be hypo one to four, used fresh. If much stronger than this blisters appear. The toning and hypo baths are used mixed by some workers. The results are much the same.

Very good prints again have been obtained by the use of pyro-potash, pyro-soda, and pyro-ammonia developers somewhat weaker than as used for plates, and with a large quantity of sulphite of soda or citric acid. With these developers clearing solution should not be stinted. Stains which five or ten minutes in the acid and alum fail to remove will sometimes disappear if the print is left in for a much greater length of time, and the picture seems in no way to suffer.

Others may have tried hydrokinone and other forms of development. Their experience will be interesting.

But by far the most important feature about Alpha paper, and the most interesting subject to treat of, is the variation obtainable in regard to colour. Warm colours are to be secured by using other well-known printing papers. Platinotype of a special kind gives a beautiful brown tint. Bromide paper by special treatment will give a colour approaching sepia, and nothing can exceed in range and variation the colours which autotype yields; but it is a distant gain to be able to secure a similar result upon a paper which can be printed by artificial light, and which can be obtained at a cost below that of ordinary silver paper.

The power to vary the colour of a print from any particular negative is held to be of great service. Without going the length of asserting, as has been suggested, that the cold, grey colour should be kept for cold or wintry scenes, and that prints in warm monochrome should be used for summer sunny scenes, still there can be little doubt that much can be done by a judicious suiting of colour to subject. There are certain fine enlargements of sea and shore waves done in shades of green—well known to most photographers. This treatment is felt as yielding a not unpleasant effect. To apply the same to portraiture would, perhaps, hardly give the same satisfaction.

There has been a rush for black and white in late years, and we have even been told that the warm colours of ordinary silver paper are held to be most objectionable by artists and men of cultivated taste. If not too assertive, the simple answer is to say that this is a mistake which a wider experience, better judgment, or closer observation—in fact, a more cultivated taste itself—would have obviated. No doubt, the glaze of silver prints is felt to be fatal to artistic quality, and there is also a widely-spread feeling of approval, and a newly discovered feeling of delight in the public mind at having its portraits so like engravings; but, as regards colours, a glance at any gallery of etchings and engravings will indicate the feelings amongst artists, and afford illustrations of lovely pictorial effects enhanced by a rendering in warm monochrome.

Practically, in the treatment of Alpha paper, it may be briefly formulated that a short exposure with normal or strong development will yield grey prints, or, more frequently, prints of an unsatisfactory greenish shade; whilst long timing (we will, in spite of objectors, call it "over exposure") will give, with restrained development, prints in warmer colours.

Upon the negative used much of the colour or the particular shade of red, brown, or purple, depends, just as in a silver print. Some will give a pinkish purple, others a mahogany red, and some negatives are much more disposed to yield the warm colours than others. It is difficult to arrive at any certainty that the use of different kinds of light—daylight, magnesium, or gas—has any distinctive effects upon colour. Nor is it seen that there is any decided or regular modification by the employment of an alkaline developer in place of iron.

It is by variations in the length of exposure and strengthening or weakening development that the great range between cold grey or bronze green and red or brown is obtained. The changes which can

be effected by treatment in the toning and hypo baths seem to depend very greatly upon the colour of the print as it leaves the developer. Those showing the objectionable greenish colour are, in my experience, the most difficult to deal with. By very strong toning and long fixation some of this can be removed, but it changes to a rather cold, bluish colour. A print developed to a red or brown gives no trouble. It can be fixed direct without gold toning, and will retain its warmth, or, if toned and then fixed, it will give any colour from the original tint through to grey.

There is, in my opinion, but one thing to do, and that is to give rather long exposures, and weaken the development. The latitude is very great, but experience with different negatives must teach the best length of time to give. If greatly over exposed, the red colour in the print is obtained at a sacrifice of brilliancy; but by a judicious use of bromide and dilution much can be done to avoid green, and to secure warmth without flatness.

The hypo bath is an important agent in producing changes of colour, as well as in brightening up the pictures. Its action does not, however, seem to be regular. Sometimes, by prolonged fixation, it will appear to remove the green colour from a print which has not been toned; at others, even an all night sitting will have no effect at all. To take the print from the hypo, treat it in the acid bath, and then return it to the hypo, has been found to change the green to a brown, but whether this would always happen I am unable to say. Other treatments have been tried. Intensification with mercuric chloride and sulphite of soda effectually removes green from an untuned print, and changes it to a very pleasant brown; but, unfortunately, grave doubts are entertained as to the permanency of such pictures.

All these different treatments are exemplified in the prints handed round. Most are simply intended to show the general quality of results to be obtained by the use of Alpha paper; some, as will be seen from the notes appended, are illustrative of the effects produced by the use of different developers, by varying the exposure, altering the light, and the other experiments already referred to. In the preparation of some of those experimental prints Mr. Seyton Scott has given very kind assistance.

In conclusion, Alpha paper is certainly worthy of trial and discussion. In addition to its own special advantages in regard to colour and cost, it is sure to commend itself to amateurs on account of its suitability for printing at evening, and for enlarging work.

There ought to be no lack of discussion upon such a subject. It is known that some here have been devotedly engaged in experimenting upon the paper, that they have made important discoveries, and have been nursing until now secrets in regard to it.

In treating of this matter an unlimited number of questions are opened up, some of practical working for Alpha-philos, and others involving subtle points for the speculative and the scientific. Our confirmed materialists will rush in with some horribly convincing physiological explanation as to exactly how and why works of art give us pleasure, or excite what is called our imagination, and we shall learn from our rising and scientific young men why a difference in colour or other quality in our negatives, or the light or heat they are printed in, yields such variations in the resulting impressions; why long exposure and restrained development set up such changes in the constitution of the image as to impart the appearance of redness to it; why and how fixing gives an additional sulphur toning; and the interesting why and wherefore in regard to many other points which those of us who fancy we have a call to art are very much in the habit of "never minding."

G. DAVISON.

NINE YEARS A TENT PHOTOGRAPHER.

Once upon a time I looked into a photographer's garret and there saw at least half a bushel of uncalled-for photographs. There were babes and children, young men and their girls, old men and women. How many hard and weary hours of posing, developing, printing, toning, and mounting, a photographer alone can tell.

These pictures told me that that photographer was too good of heart, so he let the vulgar crowd—and here they were stowed away in a box—take advantage of him. It made me mad to think of it, and I propose to tell the craft how I have kept even with such people.

In the first place I required part payment when the negative was taken, but sometimes it happened that they would be in in half an hour, or they had no small change, or something or other would happen. Well, all photographers know that the photographs on which no deposit was paid are the ones about which trouble arises. Whenever I had pictures uncalled for in a reasonable time I put them in my show-cases, turning them *upside down*. Upon being displayed thus, people would say, "Well! well! what's the matter with him? deadhead I guess;" and one would

say, "His pictures are not called for yet." It almost always had the desired effect, and they either called or sent for their pictures.

I tented nine years alone, having neither partner nor hired man. Nearly five years were spent in Arizona, and I often wondered that I was not held up and robbed. Once I lost a garment. I had travelled two long days by waggon over the dusty alkali plains and was camped on the San Francisco River at a copper mining camp at Clifton. Half of the men you saw carried "guns" (immense pistols) around their waists. I saw a man shoot through the rim of a drunk's hat to see how close he could come to his head without hitting him. Times were rough then.

The nights in Arizona in summer are generally lovely; so warm that you are comfortable in your shirt sleeves to sleep on the top of a house or on your cot out of doors. One night, being quite tired out, I took off my pants and left them just inside the tent under the skylight, which was open. The moon shone clear and bright. I slept on my blanket on the operating carpet, with my pistol under my head. There was a big dance in town that night, and I presume some rascal opened the side door, it being only tied with a string, and stole my pants. They did not contain much money, for I always hid my cash in the ground, but my watch, keys, &c. Fortunately I found a pair of overalls in the morning, so that I did not have to go out like a Yuma buck. I put my pistol up on the dark room shelf afterwards, and never had occasion to use it.

I was once camped in a little town on the Gila, Arizona. There was but one American young lady in the place, and of course all the boys were in love with her. I took five dozen cabinets of that young lady, for which the boys paid. There were dark-eyed señoritas, but they could not shine alongside the American girl.

Then I moved to a Mormon town, where I was treated very kindly, and well patronised; but it seemed heartless, cruel, hard, to see one of the leading men come one day with a wife and half a dozen children, and next day bring in another wife with another lot of children to be photographed. The passage of Scripture "increase and multiply" is the one they seem most to practise. Seems to me if they would pursue quality, instead of quantity, it would be better for humanity. Not that the Mormon children are dull; they seem like the world's children everywhere, bright and happy. The community I visited lived upon the German plan, in a community, and had their farming land at a distance. I boarded while there with a leading man who came across the plains with Brigham Young. He had two wives; they often came in my tent together. I asked them closely about their belief in polygamy. They seemed to think it was the only right way, and got along well together, living at either end of the same house—which was divided by a partition—as nicely as two church mice. But the first wife, the most refined of the two, wore upon her face in repose a sad, heart-broken look, in which my long practised photographic eye read, "there's a story untold."

I thank men for telegraphs and telephones, for railroads and newspapers, for in them I see the glimmer of the good time coming when creeds shall perish from off the earth, and knowledge and truth shall be sought everywhere. E. A. BOXINE, Los Angeles.

—Anthony's Photographic Bulletin.

PHOTOGRAPHING AT NIAGARA FALLS.

[A Communication to the Photographic Society of Philadelphia.]

SINCE the opening of the State Reservation, and the consequent demolition of the unsightly mills and buildings that formerly marred the beauty and grandeur of the place, many views, hitherto inaccessible, have been opened up. Primitive simplicity, unaided by art, is now one of the great features of Niagara, and one thoroughly appreciated by the lovers of the picturesque; another feature of the Reservation being the almost entire freedom from "fees," and the annoying solicitations of hackmen and guides.

Those familiar with the geography of the Niagara River are aware that the falls face the north and the north-east, consequently a large proportion of the views must, of necessity, be made against the light. This fact, of itself, renders the photographing of the swiftly-rushing waters an unusually difficult task. The best time of the year is undoubtedly in the month of June, when the early foliage is at its prime, and before the excursion season has fairly opened. I speak from experience on this point, having suffered from the annoyance of unwelcome "figure compositions" suddenly presenting themselves in the field of view.

At that season, the sun being in its most northerly position, the light upon the falls is at its best. Ordinarily, a bright sun is best adapted for general work, although it must be remembered that, in views of the rapids, especially from the American side, an overcast day will give much the softest results. This, I may say, is true of any view in which there are harsh contrasts.

Two great enemies of the photographer at Niagara are wind and spray. While the former holds sway it is useless to attempt any work. The latter is by no means a constant quantity, and successful views of the falls proper can only be made when it is at its minimum. Attempts to render what appear to be fine spray effects result only in hopeless fog. My experience has been that it is far preferable for the casual visitor, having but a limited time at his disposal, to eschew the difficult subjects, unless under the most favourable circumstances, and confine operations

to views readily attainable, and such "hits" of picturesque scenery as may strike his fancy.

Photographing the falls from below is attended with so much risk and discomfort that even the most ardent amateur may be excused from making the attempt; especially is this the case when the results obtained, even under the most favourable circumstances, are not commensurate with the time and labour expended. I have been informed by some of the resident photographers that, during the year, there are indeed very few days on which really good pictures of the falls from below can be made. It is useless to attempt photography at Niagara without an exposing shutter capable of giving exposures from one-tenth to one-hundredth of a second, my own experience being that with very rapid plates the best results were obtained by using as large an aperture as was consistent with fair marginal definition, and as rapid an exposure as any shutter would produce. I am convinced that a larger amount of detail is obtained in this way than where a slower exposure is made with a smaller stop. The extreme darkness of the foliage about the falls is such as to render the developing of very much detail almost an impossibility, especially so when contrasted with the brightly illuminated water. Plates showing a decided tendency to "softness" will, therefore, give better results. In order to proceed systematically, the photographer should commence in Prospect Park as early in the morning as possible, and gradually work around over Goat and Luna Islands, finishing with the Sister Islands about noon.

Views from the Canadian side are best made in the afternoon. I may remark here that neither the American nor Canadian customs officers stationed at the new suspension bridge make any objections to photographic apparatus, unless, however, the enthusiastic operator is sacrilegiously inclined and desires to profane the Dominion Sabbath, then the "blue-nose" official will doubtless interfere. The virtuous Canadians evidently draw the line at photographing on Sunday. On clear days, when the falls are comparatively free from spray, some very fine effects are to be had from a point near where formerly stood Table Rock. From a point on Clark's Island, about three-quarters of a mile above the Horseshoe Falls, a fine view of the Canadian rapids can be made. Late in the afternoon, when the shadows fall obliquely, the effect of the turbulent water is superb. For views of this character it will be necessary to increase the speed of the shutter considerably, otherwise the swiftly-moving water in the foreground will be so much blurred as to spoil the general harmony of the result.

To one fond of engineering subjects, the cantilever bridge of the Michigan Central Railway will prove both pleasing and interesting, the best point from which to make it being what is known as the "Old Maid of the Mist" landing, about half a mile above, and reached by a good road down the bluff. The walk along the bluff below the town of Niagara Falls, after passing the mills, is picturesque in the extreme, and affords some excellent subjects. I did not attempt any photographs of the Whirlpool Rapids, and, therefore, cannot say when and how the best views are to be made. From casual examination, however, I should say that the Canadian side, after about one o'clock in the afternoon, would offer the most advantages. Having thus, in a general way, given some idea of the photographic work to be made about the falls, I must say that, in a field so rich and varied, it is impossible to establish any given route or class of subjects; let the results proclaim at once the individuality of the artist.

The government breakwater, at the mouth of Buffalo Creek, offers favourable opportunities for instantaneous views of the lake marine. To those who may be interested in technical points, I will say that the pictures exhibited were all made with a Ross' rapid symmetrical lens of seven and a half inch focus, using an aperture of $\frac{1}{6}$. The shutter used was one of my own construction.

CHARLES R. PANCOAST.

THE HUMOROUS SIDE OF PHOTOGRAPHY.

[A Communication to the Birmingham Photographic Society.]

SOME few words are needed to-night by way of introduction, though I promise you they shall be short. Some lectures you know are instructive, others amusing, and there are those of a hybrid character which combine instruction with amusement; the latter have a "fine old crusted" tone about them, but I promise you that mine will fulfil all the requirements of that phrase, at all events you may take it from me that I have made no efforts but to amuse you. Possibly, there may be found some instruction lurking here and there, which you may be able to find out.

Some time back, when, as a member of the Lantern Committee, I came here prepared to do my share, several members asked me if "my paper" was ready. I replied in the negative, as I had only some lantern slides to show, but promised the paper, which I now shall read to you, with illustrations.

You may ask me why I deem amusement a suitable subject for a paper before this august and sedate Society. Well, I have an object. The affairs of a scientific society like ours may be conducted in too melancholy a tone, too humdrum, in fact. I do not say that we suffer on that score, but I do say a little humour, a few pleasantries thrown into our meetings from time to time, will draw members closer together, and dissi-

pate that awfully cold state of reserve that many of our members suffer from. One or two of the meetings have reminded me somewhat of a "Burial Club" met to bewail the loss of a member, and to vote, as cheerfully as the mournful subject will allow, the worldly gold for his decent interment. Mind you, I am only giving you my own opinion, and I'll take all the credit for it, but don't want any blame. True, all our meetings are not like this, for we have several unconscious humorists in our midst. Take, for example, the one who spoke of the dread he entertained of the difficulty of preparing a paper to read before the members. "But, bless you!" he added, after he had the paper finished, he found "there was nothing in it." There was no vote taken on the question. And then don't forget the exciting episodes of demonstration when a member says something like this, "You see it develops very quickly," and then finds something has gone wrong, and it's not developing at all. But I agree with Artemus Ward when he says, "I think, don't you know, an occasional joke improves a comic paper;" so even if we have humorists among us, there is still room for an occasional joke.

Then there are the outdoor excursions. What about that grand piece of apparatus yept "Ye Society's Changing Bag," which fogged so many plates at Dovedale? and the incident where a member dropped a lot of exposed plates into the river? Isn't that humour? Not exactly dry humour, though, although some people recommend soaking the plates before development. As regards the excursions and where to go, one has to *Pickard* (pick hard) among those on the list for a *Holiday*, it would be *Skarleesly* possible to be better arranged; it is a *Delicate* question, but still I must not *Birkett* (burke it). The expenses might be kept down by going to some place where drinks might be obtained at the *Pumphrey* (pump free) of cost, though many would not care a *Button* about that; still on a broiling day with a fairish *Heaton* (heat on), it doesn't do to be too *Cor-y* about the matter. Then there is the old villager who tells you "Harry's son (*Harrison*) will carry your luggage, and I'll show you the way as *Iliff* (I live) close by." Give him a three-penny bit, and tell him not to *Lewis* (lose) it.

I intend to-night to speak on the humorous side of photography in three heads—two sub-heads and a line in small capitals. There are incidents with the camera in the field, at home, and lantern work. The majority of my points I shall be able to illustrate by the aid of the lantern.

Those amateurs who have knocked about the county-side as I have, both as an amateur and professionally, must have come across many things the remembrance of which even now produces a grin. The various pictures I show you to-night are not given as first-class examples, nor do I deem them anything but commonplace, everyday occurrences, but they will serve to illustrate the purpose of my paper, which is to show, in spite of all the attendant difficulties, the failures, and hard work, even with successful efforts, amateur photography gives more fun and unexpected amusements than any other of the recreations adopted by the average man. Take, for instance, at the side of a stream, with bridges few and far between. You want to be on the other side, and cannot get there without two or three miles walk. It is no use to sit down and sing, "Oh, what must it be to be there!" I'll show you how it was done by our worthy Secretary—by means of a cottager's ladder and crawling across! You don't see Mr. Karleese, but there is an umbrella; and most great men are known by their appurtenances—one by an eyeglass, another by a collar, and so on, even down to our Secretary with his umbrella. In your rambles have you ever come across the county yokel "Who'll smash the whole blooming consarn if you don't take his pictur." Here he is; according to the official and authorised version of the interview, he would have done it, too! Then here is "A Horse Slaughterer's" business-card.

It is not my intention to pursue any plan of campaign to-night, but, like the busy bee, to wander from flower to flower, and collar all the pictures I can. This is not the original text, but it "kinder fits in well." The seaside affords splendid chances for humorous pictures, as far as the sands go. At Rhyl last year, in two and a half days Mr. Taylor and self secured some fifty pictures, not having a roller slide, and having to change in the pantry amongst the beef, mutton, dripping, and black-beetles; still we were satisfied with the results, and you will see by the pictures, *Under Difficulties*, *Group of Donkeys*, *Paddling*, *Sea Urchin*, *On the Sands*, *A Penny a Swing*, *Real Jam*, *Buried Beauties*, that we let nothing hinder us.

People will get in the way sometimes. Once at Hexham four men persisted in getting in my way. They wanted to be taken in the picture, they said. I advised them to go on the bridge, as they would be better taken in there. Now where that cross is on the bridge the four heads are there—mere black dots. I don't expect you can see them, but I consider they were taken in.

Possibly some of our members are cyclists: here are a few pictures. *Nap on Wheels*—observe the joyous expression of the man with nap band; *Beat that if you can*, a grand idea, a magnificent conception, spoilt by a large boot, the card on the ground, being the interesting point, all spoilt by a boot No. 13 size. *The Odd Man out*, *The Stocks*, *The Sleeping Beauty*, *The Smoker's only Match*, *The Cow and Quicks's the Word*, *Gossip*, &c. At Kenilworth, the other day, we had a circus performance; then, again, I was trying to get some scenes of amateur theatricals. The day was dull, and the stage dark and gloomy; however,

with three minutes' exposure, I secured some sort of result. Whilst taking it one lady got up and walked off the stage; the military gentleman next her asked if it made any matter. "Oh, no! tell her to come back again." A little time after the same lady, looking at the photograph, said she seemed hazy, and I replied, "I was afraid she had moved."

Now I come to photography at home. Here is *Background*, nothing but real old English "tubs" and buckets; *Teep tite still*, the baby photographer; *Impudence*, *Parcels Post*, *The Doll Family*, &c.

And now we come to the lantern as a humorist. There is very often much impromptu fun at a lantern show, owing to slides being put in upside down. That is quite a common occurrence; and when the slides of different members are put through—various sizes and shapes and remounted, with no directions how they are to be put in—fine fun is caused for every one but the operator, who hears on all sides the shout, "It's the wrong way round." I show you some twenty illustrations of what may be termed tricks with the lantern; but they are very effective for home entertainment, and the subject is capable of wide extension. This will conclude my remarks on this point—the lantern as a humorist, and will finish my paper by exhibiting the remainder of the slides I have selected for the *Humorous Side of Photography*. J. W. WELFORD.

THE THEORY OF DEVELOPMENT.

[A Communication to the Cardiff Amateur Photographic Society.]

By development of a plate, one understands the continuation and intensification of an action commenced by light. When a plate is exposed in a camera the bromide and other salts of silver are so acted upon by light as to set up an incipient state of decomposition, that is, the light seems to weaken the affinity between the bromide and the silver. I have mentioned only bromide, but the same remarks apply also to the chloride and iodide, so that when the developer is poured on the plate the separation of the two elements (silver and bromine) in the parts which have been exposed to light is effected long before the rest of the plate. It must not be forgotten that the whole of the plate is similarly affected by the developer, whether it has been exposed to light or not, and that it is only the difference in time between the blackening of the exposed and unexposed parts that makes development at all a possibility. This is a point that many amateurs would do well to bear in mind.

By a developer we mean any chemical or chemicals which have the power to reduce silver salts. These are known to chemists as reducing agents, and they are so called because all developers or reducing agents have one great property in common. They have all a great affinity for oxygen, and it is this property which enables them to reduce silver salts, and thus develop the picture. All the pyro developers in common use (for dry plates) may be considered on four legs, or to be composed of four principal parts, namely:—1. The reducing agent; 2. The corrective; 3. The alkali; 4. The preservative; all rendered active by being dissolved in the diluent water. I have a few words to say about each of these parts and will try to answer intelligently the following questions:—1. What is the use of the reducing agent? 2. What is the use of the retarding or checking agent? 3. What is the use of the alkali? 4. What is the use of the preservative? 5. What is the use of the diluent water?

1. The reducing agent has the power to separate the silver from the bromine, chlorine, and iodine, or whatever other element or elements it may be combined with. This it does by combining with the oxygen of the water contained in the developer, thus liberating hydrogen which combines with the bromine, iodine, &c., and leaves metallic silver in the form of a black powder. This black powder is the high light of the picture. The substances generally used as developers are pyrogallie acid, hydroquinone, and oxalate of iron, although many other substances could be used. A very interesting experiment is to add a little of each substance to a solution of nitrate of silver in water, and observe the different effects.

2. The retarding or checking agent. For this purpose some bromide is used, generally the bromide of potash, ammonia, or soda. This acts by forming a loose compound with the silver salts, which is much less susceptible to the action of developing (or reducing) agents than the silver salts are alone. The bromide, therefore, protects the silver salts from the developer, and thus checks the progress of development.

3. The alkali is a necessary constituent of all pyro developers. The alkalies used are usually ammonia or the carbonates of potash and soda. I should think that the carbonate of ammonia, or the hydrates of potash or soda, would also serve for this purpose. If you try to develop a plate without adding ammonia, potash, or soda, you will find that it will be a failure. Suppose you put a solution of pyro, made acid with citric or nitric acid, on a plate, you will find that no action takes place, at least not for a long time. If you now add a little ammonia, potash, or soda, you will find that the development commences at once, and the more ammonia, potash, or soda you add, the quicker the development will take place. Chemists express these facts by stating that pyrogallie acid is active in an alkaline medium.

The ferrous-oxalate developer is, however, different. If you add an alkali to that, you will make a mess of it. That is active in an acid

medium. You know that the ferrous-oxalate developer is composed of proto-sulphate of iron (ferrous sulphate) and oxalate of potash. Ferrous sulphate alone might be used, but it is not nearly so energetic as the oxalate of iron, which is formed by double decomposition between the oxalate of potash and sulphate of iron. If you take two solutions of nitrate of silver, and add to one of them a solution of ferrous sulphate, and to the other the usual ferrous-oxalate developer, you will see that the sulphate of iron takes longer to blacken the silver (that is, to precipitate the silver) than the ferrous-oxalate developer.

4. The preservative. All the developers are very unstable compounds, because they are so susceptible to oxidation. When they are dissolved in water they require something to protect them. In the case of pyrogallie acid, citric or nitric acid is used. I have said before that pyro is most active in alkaline solution. The acid is therefore added to counteract the oxidising tendency.

The ferrous-oxalate developer is usually protected by floating castor oil, or refined paraffine oil on the surface of it, and drawing off the solution with a tap or syphon. Hypophosphorous acid or hypophosphite of soda may be added (about one or two drachms to a pint), and will also keep the developer.

5. The water used. It is always the safest plan to use distilled water; but as a matter of fact I have never heard of failures through using good clean tap water.

Having endeavoured to answer the questions I set myself, I think it would be a great step in advance if photographers would try and mix their developers and select their chemicals in a more intelligent manner—not to follow the books so closely, but to ascertain why this, that, and the other chemicals are used, and in what manner they act, and to regulate their mixing accordingly; in fact, the thing to be arrived at is to see scientifically with one eye and artistically with the other.

JESSE WILLIAMS.

ON A METHOD OF MOUNTING ALBUMEN PRINTS ON ANY KIND OF PAPER.

THE impossibility of mounting albumen prints on note paper or printers' paper with the ordinary materials, is perfectly understood by all photographers. Books cannot be illustrated by albumen prints without the employment of cardboard, nor can the amateur paste his production in a letter without encountering an amount of crumpling and cockling which destroys alike the appearance of letter and photograph. An attempt has been made to obviate this difficulty by the use of gelatine dissolved in the smallest possible quantity of water, but the formula of Mr. G. W. Simpson did not in my hands yield satisfactory results. After making one or two experiments in other directions, the object being to avoid the use of water altogether, I found that a thick solution of bleached shellac in alcohol answered every requirement for any kind of paper likely to be used, as well as for cardboard, the mounted prints being perfectly flat and firmly attached. My general practice is to roll up the damp prints, as they come from the washing trays, in little bundles with the albumen face outwards, and allow them to dry spontaneously; each bundle is rolled in a sheet of note or foolscap paper. When the prints are dry they are flattened and placed in a book or portfolio, and are then ready to be trimmed. After this operation the thick shellac is applied and they are mounted in the usual way, the only precaution being that the shellac must not be allowed to get on the face of the print, as there is no means of removing it; for if alcohol be applied, it penetrates the paper and dilutes the varnish, which then makes its appearance on the face of the print in spots. The prints are kept under moderate pressure till dry. The varnish allows a certain amount of adjustment on the mount, quite enough leeway for one accustomed to such operations.

The prints by this means are very firmly attached to the paper; there is no possibility of any injurious reaction taking place between the varnish and the albumen film, for they never come in contact; the print is protected at its back by the most durable varnish with which we are acquainted, and it lies flat. At present I know of only one drawback to the process proposed; if it is desired to remove a print from its mount, of course alcohol must be employed instead of water.

Prints mounted on note paper, printers' paper, and cardboard accompany this communication.

[The specimens sent by Professor Rood are remarkably good, and free from curl and cockling.—*Eos. of Anthony's Bulletin.*]

PROF. O. N. ROOD.

Department for Inexperienced Photographers.

WHAT IS THE USE OF A DIAPHRAGM IN A LENS?

THE diaphragm, often designated the stop, is an opaque plate having in it an aperture of smaller dimensions than the lens. Its function consists in debarring the transmission of all light except what passes through it, and by its position it can compel one or another portion of the lens to be instrumental in forming the image in the camera. The best part of the lens is, therefore, by its agency brought into use.

The diaphragm is employed for a twofold purpose: it flattens the field by rendering the margin of the picture sharp at the same time that the centre is in good focus, and it gives depth of definition by rendering objects reasonably sharp, whether such objects are situated near to the camera or at a great distance. These advantages are obtained at the expense of illumination. The smaller the diaphragm is, the greater will be the depth or penetration obtained.

To illustrate these uses: let the camera be directed towards a wall, row of houses, or a landscape, and focus the centre without making use of a diaphragm, or, if any, the largest one belonging to the lens. Examine the image on the ground-glass by a magnifier, and it will be found that the sharpness by which the centre is characterised is confined to a more or less limited area beyond which indistinctness prevails. Now insert diaphragms in succession each smaller than the other, and the area of sharpness increases until it embraces the whole of the plate.

The use of the diaphragm in conferring depth or penetration may be shown by arranging a group in front of the camera in such a manner as that some shall be nearer than others. Focus the nearest figure sharply, and in most cases it will be found that all the others situated behind this one will be indistinct and out of focus. By proceeding as before directed, that is, inserting one diaphragm after another in succession, eventually one will be found which will bring the nearest and most distant figure into sharpness simultaneously. This applies equally to landscapes as to figures, and indicates the method by which distant hills and objects in the foreground are rendered equally sharp.

We do not here imply that it is always advisable, or in good taste, to make the distance extremely sharp, for, on the contrary, it is frequently desirable that it should be subordinate to the leading theme in the composition so far as regards sharpness.

In a single achromatic lens the stop must be placed next to the flat or concave side, and, with one exception, to the outside of the lens. This exception is in the case of the lens being of an extremely deep meniscus form, when it is often better that the convex surface shall be directed towards the subject. A practical outcome of this will be found in the case of a wide angle compound, from which it is desired to remove one of the lenses in order to obtain a longer focus, when the back lens may be removed, leaving the front lens alone in its place. But a single trial will determine whether this is the better position with any given combination.

In a rapid combination the position for the diaphragm is about midway between the lenses; yet it is sometimes attended with advantage that its position be shifted a little nearer to the front. We may here observe that according to the position of the diaphragm in such lenses, so will be the flatness of the field on the one hand and the production of or freedom from linear distortion on the other. With portrait combinations the flattest field is obtained when the diaphragm is near the front lens.

In single landscape lenses it is well to have the diaphragm at the maximum distance from the lens—this ensures flatness; but it is also well to have the power of bringing it close to the lens in order to minimise distortion when taking architectural subjects.

The shape of the aperture should invariably be circular.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 4586.—“A New or Improved Holder for Photographic Plates.” E. H. WHITE.—*Dated March 28, 1887.*

PATENTS COMPLETED.

A NEW OR IMPROVED PROCESS FOR PREPARING THE NEGATIVES REQUIRED FOR REPRODUCING PHOTOGRAPHS IN COPPERPLATE, LITHOGRAPHIC, OR PRINTING PRESSES.

No. 5596. LORENTZ ALBERT GROTH, K.G.V., 30, Finsbury-pavement, London, E.C.—*April 22, 1886.*

HERETOFORE it has been impossible to reproduce photographs in printing machines because of their smooth surfaces. The object of this invention is to give them a suitable irregular surface by means of specially prepared negatives.

In our Patent, No. 5595, dated same date, for reproducing photographs in copperplate, lithographic, or printing presses, I have already described one method of preparing the negatives, namely, by rubbing powdered oxide of zinc or oxide of bismuth over the surface of specially prepared pigment paper. They can, however, be prepared in different ways all leading to the same result, of which the following is one:—

On a level surface painted black or white is fastened by means of glue, grains of wheat, rye, lentils, beans, rice, barley, sand, or any suchlike material, from which plate a very reduced photograph is taken which represents a more or less irregular surface called a “corn surface,” by means of which a negative is obtained.

With this corn negative in conjunction with the half tone a corn negative is obtained from which the blocks or plates are prepared,

Instead of using the surface covered with grain, &c., a design by hand or with the guillochir machine may be used.

The same result may be obtained from a copper or glass plate ground or roughed by a sandblast machine, inked as for copperplate printing, from which a few good copies may be taken on vegetable or prepared paper, and from which a negative can be taken by means of which corn negatives from half tone originals can be produced.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—A new method of preparing the negatives required for reproducing photographs in copperplate, lithographic, or printing presses, consisting in fastening on a smooth level surface grains of wheat, rye, lentils, beans, rice, barley, sand, or other suitable material, or a design suitable for the purpose, and from which plate a photograph on a very reduced scale is taken having a corn surface, by means of which, in conjunction with half tone originals, corn negatives can be produced, substantially as hereinbefore described.

A NEW OR IMPROVED PROCESS FOR PREPARING THE NEGATIVES REQUIRED FOR REPRODUCING PHOTOGRAPHS IN COPPERPLATE, LITHOGRAPHIC, OR PRINTING PRESSES.

No. 5654. LORENTZ ALBERT GROTH, K.G.V., 30, Finsbury-pavement, London, E.C.—April 24, 1886.

THIS invention is a modification of those already filed by us on the 22nd day of April, 1886, Nos. 5595 and 5596, the object of which is to prepare the necessary negatives for reproducing photographs in copperplate, lithographic, or printing presses.

The operation is as follows:—

A plate or cylinder of copper or steel coated with asphalt or other thin plastic substance, in conjunction with a corn or irregular surfaced negative (as described in my former applications), is exposed to the light and developed in the usual way, and then etched by perchloride of iron acid or by means of electricity.

An uncoloured transfer paper prepared with chalk is then strongly pressed against the plate or cylinder, so that the raised parts are perfectly impressed into the transfer paper.

By means of a negative pressed against this transfer paper and exposed to the light a copy with a corn or irregular surface is produced as described in our Patent, 5595, which, after being touched up (if necessary) with lithographic chalk, can be transferred direct to the stone or zinc, or a negative may be taken which can be used as a medium for making the plates in the usual way.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The preparation of negatives for reproducing photographs in copperplate, lithographic, or printing presses, consisting in preparing plates or cylinders with peculiar corn or irregular surfaces on which an uncoloured transfer paper prepared with chalk is pressed, the impressed copy of which in conjunction with any negative serves for producing a positive with a corn or irregular surface, by means of which the plates can be produced as described in our former Patents, Nos. 5595 and 5596, of 1886.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 7121. GEORGE LOWDON, Reform-street, Dundee.—May 27, 1886.

THIS improvement relates to cameras which are intended to be carried in the hand, and is particularly suited for instantaneous photography.

The camera is made so that when closed it resembles a book. In the back of the camera, which is made of wood and framed up, I fix the lens so that it is quite concealed from view, and dispense with the projections and fittings generally used, and in the back I fix a traversing shutter for the instantaneous working of the lens.

Inside the book or camera I attach a flexible body of dark cloth, indiarubber, or other suitable material, at the narrow end to the frame surrounding the lens, and at the wide end to the external boards, thus allowing the covers of the book to open sufficiently to receive the slides containing the prepared plates. This book camera is held open by means of a hinged diaphragm, which when expanded rests on the two ends of the parts representing the ends of the book.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. The improved construction of hand photographic cameras by making them in the shape or form of a book, substantially as hereinbefore mentioned, described, and represented in the drawings annexed. 2. The improved application of roller-slide apparatus to photographic cameras of the character hereinbefore described and represented in the drawings annexed. 3. The improved general arrangement, construction, and application or representation of a book for photographic cameras for hand or detective use, substantially as hereinbefore described and represented in the drawings annexed.

WAS THERE NO COPYRIGHT?—At the High Court of Justice, Chancery Division, Mr. Turner, on behalf of the plaintiff (Mr. Paine, Aylesbury), moved, *ex parte*, for an interim injunction to restrain the defendants from multiplying copies of, or offering for sale copies of, a photograph of Manor House, the residence of Baron Rothschild, at Waddesdon, Buckinghamshire, in which the Prince of Wales is seen coming out of the building. The plaintiff carries on business as a photographer at Aylesbury, and the photograph in question was taken by him, he being under an undertaking not to publish the same without the consent of Baron Rothschild. The defendant Stephens is also a photographer, carrying on business at Aylesbury under the style of the American Photographic Company, and Armstrong, the other defendant, likewise carries on a similar business at Aylesbury. The defendants having obtained a copy of the photograph in question, were said to be now offering copies for sale at sixpence each. Mr. Justice Kay, upon the plaintiff giving the usual undertaking in damages, granted an injunction over Friday week.

CAMERA CLUB.

AT the meeting held on the 24th ultimo, the CHAIRMAN (Mr. W. Ashbury Greene) referred to the early departure of Mr. W. K. Burton for Japan, and the meeting very cordially supported an expression of hope that a successful future lay before him.

The CHAIRMAN also drew attention to some silver prints sent by a country member, Mr. R. H. Bow. These had been fixed by ammonia.

Mr. H. H. O'Farrell exhibited an ingenious lantern camera in which a base-board and rackwork were dispensed with, the front being worked out upon hinged rods.

Mr. G. DAVISON then read a paper on *Alpha Paper* [see page 200].

Mr. A. R. DRESSER said that some prints which he had intensified with mercury and sulphite of soda had not faded after an exposure to direct sunlight for several days. He had used Alpha paper since 1884, and preferred to tone with hypo, gold, and platinum in one solution. He had used all sorts of developers, with results which he proceeded to show to the meeting. Mr. Dresser also showed a useful frame for the purpose of printing in clouds on bromide and platinum papers, particularly in the difficult circumstances when an oval or other shaped mask was being used.

Mr. J. E. AUSTIN then followed, especially in regard to enlarging upon Alpha paper. Some very striking framed enlargements he had recently done were exhibited, the sizes ranging as high as two feet by one and a half foot. He said that enlarging had become his hobby-horse, and he found Alpha paper the most suitable of any for his purpose. Silver, platinum, and carbon required a solar camera for this work. A half-plate or under was the most suitable size to enlarge from; the smaller lenses gave much greater depth and crispness. The negative should be full of detail. Harshness was fatal to success. The greater the enlargement required, the greater the necessity for a flat negative, because for marginal definition a smaller stop was required; hence there was a loss of light. He used an 8×5 rapid symmetrical, working a $\frac{1}{2}$, and found it best to focus for the part half way between the centre of the plate and edge. On a very poor, flat negative, smaller stops will improve matters. In cutting such large-sized pieces from a roll of Alpha paper, he laid it upon glass and used a guide. Treated this way, it was not so liable to tear in subsequent operations. For very large work, to make a safe edge to lift it by, he wetted a margin and turned it over, the gelatine securing this double thickness. The paper expands in the solution; twenty-four inches will expand to twenty-five. As development proceeds rapidly, it is necessary to lift these large prints just before they appear to be developed. He found iron the best developer, as giving purer whites. Pyro and potash were to be used with advantage for chalky negatives. In developing large work a wide soft brush was useful to keep the print flat. He found it necessary to allow the acid bath to get at both sides of the paper, or markings showed when dry. He found a great variety of tones result from intensification, according as sulphite of soda, carbonate of soda, carbonate of potash, or bisulphite of potash were used after the mercuric chloride. A very much over-developed print could be improved by treating with a very weak solution of bichloride of mercury.

Mr. DOUGLAS P. RODGERS considered the paper extremely useful, enabling printing in almost any desired tone by artificial light. A good print could be obtained from any negative, thin or dense. There was the one drawback that the exposure had to be learned anew for each negative. Alpha paper gave, in his hands, better detail and half tones than the bromide papers. Mr. Rodgers here showed a number of examples, ranging in tone from a black to a bright red, and gave several formulae to the action of which he ascribed these colours. The same tones were obtainable in enlargements by the lantern, using the limelight, the exposure varying from twenty seconds to three minutes. He agreed that the print always passed through a red stage in developing, but if it had only received a comparatively brief exposure, all the detail would not be out until the deeper shadows had assumed the black colours; so that if the development of such a print were arrested at the red stage, only half a picture would result. On the other hand, given a full exposure, and it was possible, by the use of a suitable developer, to produce black or red tones at will. He had used the mercurial intensifier to obtain warm tones two months ago, and had not found his pictures fade. Provided they were permanent, he considered this a very useful modification of the working, as the process could be performed in full daylight, and the exact colour judged—a thing quite impossible in the yellow light of the developing room. He did not find an acid cleaning bath necessary, the acidity of the developer being sufficient to prevent any staining of the print. The toning and fixing with gold in the hypo he had

found rather uncertain in action. Sometimes it toned and sometimes not, without any apparent reason.

Mr. LYONEL CLARK entered into a very interesting discussion of the causes of red and green images in development, and touched upon other points of scientific interest.

Mr. H. J. GIFFORD dwelt upon the permanence of bromide prints.

Mr. DAVISON said there might have been some error in his intensification experiments, as the treated prints had darkened so easily. He did not think that the colours obtained by Mr. Rodgers were traceable to the peculiarities of his developers, to which he ascribed them, but simply to the fact that those developers were strongly restrained and the prints fully exposed. He thought some of Mr. Austin's enlargements great triumphs, but many of his remarks on enlarging seemed to be open to criticism.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of the above was held at the Technical Schools, Bridge-street, on Thursday, the 24th ultimo,—Vice-President W. J. Harrison, F.G.S., in the chair. There was a good attendance.

The minutes of the last meeting having been read and confirmed, Mr. Jonah Pumphrey was elected a member, and Messrs. Birkett and Townshend were nominated for election.

After some discussion it was proposed and seconded that the excursion on April 9 should be to Bridgnorth, Mr. Welford consenting to be leader for the day.

Amongst the exhibits a number of photographs and slides of scenes taken during the Queen's visit to Birmingham were shown by Messrs. Delicate, Pickard, Pumphrey, and Tylar, which were very interesting.

Mr. Welford then gave his paper on *The Humorous Side of Photography* [see page 202].

At the conclusion of the paper, which was very amusing and entertaining, the VICE-PRESIDENT, after thanking the lecturer, announced that the subject of the next paper, on April 14, would be *Enlargements*, by Mr. E. H. Jaques.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

A STATED meeting of the Society was held on Wednesday evening, March 2,—The President, Mr. Frederic Graff, in the chair.

The paper for the evening, written by Mr. Charles R. Pancoast, was read, in his absence, by Mr. John G. Bullock, the subject being *Photographing at Niagara Falls* [see page 202], illustrated by about twenty-five lantern slides taken from negatives made by Mr. Pancoast.

Mr. FREDERICK E. IVES gave a short address on the subject of *Photographing by the Aid of the Phosphorescent Tablet*. He said, Photography by the aid of the phosphorescent tablet is not a new discovery, having been known since 1880. It is not even a practically useful method, and is interesting only from a scientific point of view. My own experiments with the method having resulted in the discovery of certain facts not previously known, I have been persuaded to show the results and make some remarks concerning them. The facts already well known are that Balmann's phosphorescent paint, which probably consists chiefly of sulphide of calcium, in a suitable vehicle becomes luminous when exposed to light, and the light emitted acts powerfully on photographic sensitive plates; also that heat releases phosphorescent energy. Solarised phosphorescent tablets have been used as a source of light for contact printing in the dark room, and negatives have been made by exposing the tablet in a camera and then making a contact exposure on a photographic sensitive plate in the dark room. Such a photograph I now show. It has a somewhat granular appearance, due to the coarseness of the particle of sulphide of calcium, and although the lines are partly sharp they appear surrounded by a sort of halo. The Editors of THE BRITISH JOURNAL OF PHOTOGRAPHY, in a recent editorial, advanced the theory that this effect was due to a spreading of the phosphorescence, and that it would be impossible to obtain a sharp camera photograph by the aid of the phosphorescent tablet. My belief is that the phosphorescence does not spread, and that the effect is due merely to the fact that the luminosity of the phosphorescent coating extends to considerable depth, and the light from the lower part of the layer acts diffusely, because it is radiated from a point at some distance from the surface of the photographic sensitive plate. To test this I exposed a tablet in the sunlight until fully solarised, then removed it to the dark room and placed it in contact with another tablet under pressure. It was impossible to discover any communication of phosphorescence by contact, and if any occurs it is insignificant. I also observed that prints and camera impressions on my tablets appear perfectly sharp to the eye, and found that they could be reproduced sharply by photographing in the camera. I therefore conclude that it is possible to make sharp camera photographs by the aid of the phosphorescent tablet, but that the method has no value, because it is always easier and better to make photographs in the usual way. It has been suggested that the tablet might offer some advantage in the reproduction of coloured objects. It is true that the colour sensitiveness is not the same as that of silver bromide, but the difference had been found to be altogether in favour of the silver bromide. The second known fact that I mentioned is that heat releases (exhausts) phosphorescence. It does not appear to have occurred to any one that this might be made a means of producing camera pictures by the action of the heat until I discovered that the obscure heat rays of the linelight spectrum produced a strong impression on a solarised phosphorescent tablet. I succeeded in producing heat pictures of objects under certain conditions, which are described in a communication to the Franklin Institute, and published in the *Institute Journal* for this month.

Mr. Ives showed on the screen several photographs, among which was one showing some buildings made by the use of a phosphorescent tablet in the camera, and another in which a metallic object had been photographed by the action of reflected heat rays on the tablet in the camera.

LEEDS PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of the Society was held on the third ultimo,—Mr. T. W. Thornton, Vice-President, in the chair.

THE CHAIRMAN then called upon Mr. Warburton to read his paper on *Gelutino-Bromide Emulsion and Plate Making*.

In the course of his remarks Mr. WARBURTON said, It seems to me a pity that there are not more in a Society like this who are their own plate makers, and I sincerely hope that their numbers will increase; it is for this reason that I have ventured to string together a few remarks on the subject. There is far more pleasure to be derived from photography when one knows that the finished picture is all his own work, and not exposed and developed by one person on a plate made by a second, and printed on paper prepared by a third. I should advise beginners to always make the same quantity of emulsion, say, twenty ounces, which is a convenient quantity, and not too bulky to wash thoroughly. Your flasks, beakers, and jars can be adapted for this quantity, and, when done with, should be thoroughly cleansed and put away till wanted again. Before actually making a batch of emulsion it will perhaps be as well to say a few words on the apparatus, &c., necessary. If a room can be set apart for the operation, at least until the emulsion is made and the plates are dry, so much the better. Let the room be made quite dark and then lighted only by artificial light, which need not be used very sparingly, provided it is of the right sort. As to the apparatus, a few flasks and beakers, or, what is almost better, two or three thin jam pots, a gas stove and tin pan, to serve as a water bath, a funnel or two, a few pieces of fine linen and chamois leather, complete the apparatus necessary for emulsifying and boiling. For washing, a piece of canvas, a hair sieve, a large basin of water, and a silver spoon, are necessary. For coating, the only additional things required are a pneumatic plate holder, a levelled slab of slate or glass, and a ladle to measure the emulsion poured on each plate; a thermometer will also at times be useful. I will now suppose that ten ounces of emulsion are required—only a small quantity, but sufficient for my illustration this evening. We shall require first the silver solution, as follows:—

Nitrate of silver.....	100 grains.
Distilled water	1 ounce.

This we place in a small flask.

The next solution required is the bromised gelatine, containing—

Ammonium bromide	60 grains.
Potassium iodide.....	4 "
Nelson's gelatine.....	15 "
Distilled water.....	3 ounces.

Hydrochloric acid, 14° ... Sufficient to make distinctly acid, say, about 3 or 4 drops.

Before emulsifying, this solution must be warmed, and also the silver solution; place both flasks in the water bath until they nearly reach the boiling point, and then, by means of a glass funnel passed through a cork fitting into the ring of a retort stand, and a bit of glass tube attached to the funnel by means of a piece of pure rubber tube, you add the silver solution to the bromised gelatine, swirling the flask round whilst the silver solution is running in. The silver solution run through, the emulsion is placed in the water bath to boil. If the boiling is continued from twenty minutes to half an hour you will have a plate of fair rapidity, and one that will give you a vigorous negative; by using less acid in the bromised gelatine and extending the time of boiling you will obtain plates of greater rapidity. Whilst the emulsion is boiling the bulk of the gelatine should be placed in a jam pot to soak.

Nelson's No. 1 gelatine	80 grains.
Coignet's gelatine.....	100 "
Water	2 ounces.

After the emulsion has boiled the required time take it out of the pan and allow it to cool for a while; when cooled to about 150° add it to the gelatine which has been soaking, this will soon dissolve, when the pot should be placed in cold water to hasten the cooling and cause the emulsion to set. After setting, the emulsion is scraped out of the pot with a silver spoon or a strip of glass, and squeezed through the canvas on to the hair sieve, placed in a large bowl of cold water; change the water once or twice, and leave the shredded emulsion to steep for twelve hours, changing the water a few times during that time, after which allow the emulsion to drain some time so as to get rid of as much water as possible; it may then be remelted at a temperature of about 100° to 120°, and, after the addition of half an ounce of methylated alcohol, it is ready for coating the plates. If it does not measure ten ounces make up to that quantity with water. If the plates are old or spoilt negatives they should be placed in a hot and strong solution of soda until the films come off, then thoroughly rinsed in cold water, rubbed with a cloth dipped in tripoli powder, rinsed again, and dried on a cloth free from fluff; previous to washing the sharp edges of the glass should be taken off by drawing the edge of one glass over the edge of another, and thus two plates are done at the same time. With regard to a substratum on the glass, this is not always recommended, but it will be found best to use one, as frilling is less liable to occur. The best to use consists of white of one egg, water, sixteen ounces. When the substratum is dry the plates may be coated with emulsion, but before coating it will be necessary to filter through chamois leather. This is best done by tying the leather across one end of an Argand lamp chimney, the emulsion is then poured in the chimney, and if slow in running through the lips may be closed round the open end when, if pressure is brought to bear on the emulsion by blowing, it will easily filter through. The best way to coat the plates is to place them on the pneumatic holder and, by means of a ladle holding the proper quantity of emulsion, pour it on the plate; a glass rod may then be used to cause the emulsion to flow into the corners of the plate, when it may be set on the levelled slab to set; it should then be taken to the drying box, if one is used, but the plates will dry perfectly if they are left leaned against a number of bottles placed on a table; in this way I have dried many scores of plates. In conclusion, I would say to those who have a desire to prepare their own plates, "Do not attempt it unless you feel that you have a love for the work and a desire to see your pictures as much as possible your own work; do not attempt

It merely for the sake of economy, and do not be discouraged by a failure or two, and success will certainly follow."

In the discussion which followed, the CHAIRMAN said that he quite agreed with the remarks which had fallen from Mr. Warburton with respect to the pleasure that was to be derived from emulsion and plate making; indeed, every amateur should, in his opinion, make his own plates, if he really wished his pictures to be considered his own work. With respect to the practical part of emulsion making, he (the Chairman) differed somewhat in the manner in which he prepared his emulsion to that which had been explained to them; in the first place, he always added his silver nitrate in crystals to the bromised gelatine, stirring until they were dissolved; he did not boil longer than ten minutes, in which time he could get sufficient rapidity; this, however, might depend to some extent upon the gelatine and the more or less acid state of the emulsion. He did not use a substratum, and he had never found one necessary.

Mr. FORDSMITH said he always used a substratum; he believed it was the best preventative against frilling; he had also found that much of the glass in use for negatives was in itself not level, and thus caused unequal thickness of films.

Mr. RODWELL said he believed the simplest and, in his opinion, most efficient mode of adding the silver salt was in the shape of crystals, the bromised gelatine being contained in a hock bottle, which was then shaken until the crystals were dissolved; it was then placed in the hot water to boil; he had found a hock bottle to bear the boiling without breaking, and its non-actinic colour was a safeguard against stray light. With respect to drying, he preferred a drying box through which a current of air could be sent heated to about 70° or 75° Fahr.

Mr. BASS said when he commenced to make emulsion he was led to believe that it was necessary to churn the emulsion up whilst the silver solution was being added, and for this purpose he had made a mixing apparatus with jiggers and whisks, which he had since found quite unnecessary. All amateurs should prepare their own plates; given a finished picture, he believed seventy-five per cent. of the credit should go to the makers of the plate and paper on which it was printed; of course this must be understood to apply only to the technical qualities of the picture, as artistic qualities might exist in a high degree without technical excellence, and *vice versa*.

The next meeting of the Society will be held on Wednesday evening, April 6, at the Grand Restaurant, Boar-lane, Leeds, at seven p.m., when the President (Colonel Harding) will deliver a Presidential address.

Correspondence.

Correspondents should never write on both sides of the paper.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

To the Editors.

GENTLEMEN,—At the commencement of the present year a circular on the subject of the forthcoming Photographic Convention was sent to the Secretaries of all the Photographic Societies whose addresses had been published. A paragraph in the circular ran as follows:—

"With a view of making the Convention thoroughly representative, I shall be glad if your President, or one of your members nominated for the purpose, will represent your Society at the Committee Meeting, to be held during the week of Convention."

The intention has been to endeavour to put the Convention upon a firm footing for increased usefulness beyond the "outward and visible sign" of an enjoyable holiday, combined with instructive knowledge derived from the evening meetings. The object is, first to make the Convention in every respect thoroughly representative.

It must be obvious that a body of this kind, commanding the entire confidence of the professional and amateur alike, would be in a position to effect considerable good. There are many questions not partaking of a legal nature, materially affecting the interests of the photographic fraternity, that could with advantage be discussed by, and arbitrated upon by such a body, even if the meetings were held only during the week of Convention. It is unnecessary here to summarise the good and useful work that might be done beyond what I have merely hinted at. I am more immediately concerned now in urging those Secretaries who have not already done so to send me at an early date the name of the gentleman chosen by the members of their Societies to represent them at Glasgow in July next.—I am, yours, &c.,

J. J. BROWNISHAW.

Albert-road, Walthamstow.

A NEW LANTERN SLIDE CARRIER.

To the Editors.

GENTLEMEN,—It was with some little surprise that I read Mr. Bridge's letter in your last issue, in which he asserts that the carrier described by me in one of the annuals is not original, having been suggested and used by him and his colleague, Mr. W. Brooks, since the year 1884. I find, by reference to my note-book, that my first carriers of this description were made in April, 1883. Some months after that date I showed them

to Mr. W. Brooks, who much admired them, and stated his intention of trying them for his own work. With this circumstance in my mind, I wrote last Friday to Mr. Brooks, sending him Mr. Bridge's letter and inviting his comments upon it. To-day he writes as follows:—

"As far as my memory serves me, you showed me your carrier at the South London Lantern Meeting, which always took place on the first Thursday in January, I think it was in 1884, and I at once made about one hundred. I was not aware that Mr. Bridge made any before that date."

I may add that the first carriers were made of Willesden paper, and that each carrier was provided with an opening (closed by a piece of wood) for the admission of the slide, as described by Mr. Bridge. I quite acquit that gentleman of anything more serious than a *lapsus memorie*, and feel glad that the little contrivance reached the hands of one who appreciates the convenience which it affords.—I am, yours, &c., T. C. HERWORTH.

45, St. Augustine's-road, Camden-square, N.W., March 28, 1887.

"THE RIGHT TO THE NEGATIVE."

To the Editors.

GENTLEMEN,—Under the circumstances mentioned by your correspondent, Mr. Debenham, in your last issue, the individual referred to can have no more claim to the negatives than to the camera and lens with which they were taken. If I were threatened in a similar manner, I should at once come to the conclusion that a person who had made a ridiculous demand would certainly order no more copies, and settle the question of "right to the negatives" by dropping them into a copper containing boiling water, in which a packet or two of Manby's cleansing crystal had been dissolved.—I am, yours, &c.,

F. A. BRIDGE.

East Lodge, Dalston-lane, London, March 29, 1887.

DOUBLE PRINTING AND RETOUCHING.

To the Editors.

GENTLEMEN,—Permit me to express my sincere thanks to Mr. Macbeth for his remarks regarding double printing and retouching, and I do hope that a great many photographers will agree with his views and consider negative retouching as it is done nowadays only as a means to please the customers in general.

I am afraid so-called composition photographs, as well as hatched up negatives, resemble too much those groups and portraits seen at a cabinet of waxworks to be compared with the painters' or sculptors' art, and photography can only approach the latter by good lighting and posing the object and by obtaining a negative which will give a satisfactory print without any stippling, &c.—I am, yours, &c.,

OVER-WEARY.

Liverpool, March 29, 1887.

"THE BRITISH JOURNAL OF PHOTOGRAPHY," No. 1403.

To the Editors.

GENTLEMEN,—1403 is last week's. It contains a portrait of Mr. W. K. Burton, which is so excellent that every person concerned in producing it may be fully congratulated.

It contains also a paragraph calling attention to the admirable subjects for the camera to be got by early visits to several markets. This is common-sense, and therefore good advice.

It contains also a recommendation that two days should be employed away from home in taking six exposures; the first day in fixing their locality, and by a compass deciding upon what time of the day to visit them. This is by an American gentleman to American photographers, and I feel I have nothing to do with it. Were it addressed by any one to London amateurs, I guess I should quiz it. Londoners, Gentlemen, have a site that gives more scope for subject than any place in the world. I belong to a coterie that contemplates weekly excursions for exposure making. I fancied my compatriots looked at me cynically if not pityingly when I said, "If they decided on Limehouse, Wapping, Greenwich, or the river generally, I would join them; but if they contemplated glades, with beech-trees, and rustic houses, twenty miles from town, they must excuse me."

I some time since decided upon spending a week in town in May, with the sole object of trying some of its thousands of fine studies, on quick plates, with a good lens, and an exceedingly rapid shutter. With this object in view, I thank you most heartily for the mention of early morning markets. If I cannot get a dozen good subjects on a fine morning before breakfast I am a duffer.—I am, yours, &c.,

WILLIAM ADCOCK.

Melton Mowbray, March 28, 1887.

Exchange Column.

* * *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Studio chair with changing backs wanted in exchange for a burnisher.—Address, PHOTOGRAPHIC, Chardstock, Dorset.

A burnisher, nine-inch bar, in exchange for a $8\frac{1}{2} \times 6\frac{1}{2}$ single lens by good maker, or magic lantern.—Address, H. HOLMAN, Banff, N.B.

I will exchange a complete set of limelight apparatus for a whole-plate portrait lens.—Address, H. BROOKE, Studio, Shepton Mallet, Somerset.

Ross' No. 3 quick-acting C.-D.-V. lens, exchange for No. 6 or 7 Ross' portable symmetrical.—Address, C. H. L., Forest-cottage, Three Bridges, Sussex.

Gem camera, twelve lenses; Victoria camera, our lenses; and Ross' 5x4 instantaneous doublet. Wanted, Dallmeyer's 3b patent.—Address, American Studio, Mold.

Quarter-plate instantograph camera, three double backs and tripod. Wanted, good mechanical or coloured lantern slides.—Address, PROCTER, Hotspur-street, Tyne-mouth.

will exchange 12x10 tourist camera, with 12x10 rapid rectilinear lens, for a portable studio, complete.—Address, WALLACE FORD, 9, Hartley-street, Burnley-lane, Burnley, Lancashire.

Wanted, whole-plate rapid doublet or offers (lenses), for twenty-eight painted and six rack astronomical lantern slides.—Address, COUCH, 6, Berkeley-street, Piccadilly, London, W.

Voigtlander lens, for 18x16, would exchange for two second-hand Seavey backgrounds, seascape and interior preferred.—Address, C. E., Kemp & Co., Infirmary-street, Edinburgh.

Wanted, a good half-plate rolling press or burnisher in exchange for magic lantern oil or limelight, six-inch condensers.—Address, W. B. CASSINGRAM, 9, St. Peter's-street, Tunbridge Wells.

Will exchange twelve-inch square leather-bellows camera, by Rouch, latest improvements, single and double dark slides. Wanted, catant leather-bellows camera by good maker.—Address, THE STUDIO, Silver-street, Westminster.

Will exchange a Voigtlander's whole-plate lens and a half-plate camera, with three double dark slides, for 12x10 Ross' rapid symmetrical or a Dallmeyer's rapid rectilinear.—Address, E. GREGSON, Imperial Studio, Bedford-street, Halifax.

I will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, from 1879 up to present date, for half or whole-plate view lens, half-plate camera for outdoor use, or half-plate rolling press and cameo press.—Address, G. MASTERS, 17, Elcot-avenue, Commercial-road, Peckham, London, S.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

James Waddington, 131, Montague-street, Blackburn, Lancashire.—Four portraits of Rev. R. P. Ashe, B.A.

S. A., O. WILLIAMSON, G. B. J.—See article in the present number.

T. H. M.—Nothing is better than a thin solution of gelatine used in the manner that has so frequently been given in the JOURNAL.

H. L. (Ackworth, Pontefract).—The best work on the subject is Harwich's *Photographic Chemistry*, published by Messrs. Churchill, New Burlington-street, W.

J. H. M.—The procedure is just the same. The immersion in the acid need be very short. Only a very slight washing is required, and then the negative may be quickly dried, so that no injury need be incurred if care be exercised.

MICRO.—With a quarter-inch objective the light you have been trying with is quite insufficient. As you appear to be a novice in photo-micrography, you had better begin with a low power, say, one or two inches, and use neither eyepiece or supplementary lenses.

R. STROUD.—The excessive coldness in tone of the gelatino-bromide print is due to its being under exposed and forced in the development. If the exposure had been one-third longer the tone would have been much warmer. The care you take in the fixing and washing will no doubt secure permanency.

F. L. L. asks: "Will you kindly inform me, through the medium of your paper, how the blacking for the inside of dark slides should be made?"—Lampblack, or, preferably, what is known as drop black, mixed with equal parts of ordinary negative varnish and methylated spirit forms one of the best materials that can be employed.

INS.—1. Any of the commercial shutters will answer the purpose. That indicated by your friend is a very good one.—2. An iris diaphragm is a series of flat plates working on pivots which can all be brought simultaneously to a centre so as to open or close the aperture.—3. The Wollaston shutter is described on page 486 of our volume for 1886.

M. LE TOURNEUX writes: "I should esteem it a favour if you would kindly give me the address of a firm, through the medium of your columns, where I could procure gelatinised paper suitable for making transfers for photo-lithographs."—Paper specially prepared for photo-lithographic transfers is supplied by Mr. E. Liesegang, Düsseldorf, Germany.

A. C. WARNER.—You will have to pay a duty of about forty per cent. on your photographic apparatus when you take it into America. If you can succeed in convincing the officials that it is only for your own use it will be admitted free of duty, but if the apparatus be new we fear you will not be successful in this. With old-looking or shabby appliances you might succeed.

WM. SUTCLIFFE says: "I am in possession of a lens which has marked on the flange 'Steinheil, Aplanat, 23 Lin.' Would you kindly let me know, through your 'Answers to Correspondents' column, about this lens, and also what '23 Lin.' means? I fancy it refers to its focus, of which I am ignorant.—This means the diameter of the lens. A 'lin' is practically the one-twelfth of an inch, consequently twenty-three lines is, roughly, about one-and-three-quarter-inch.

II. C. M.—We could only ascertain the candle power of the ribbon enclosed by photometrical experiment. Of course the power of the light must depend upon how the magnesium is burnt. If the ribbon be pointed downward the combustion would be more rapid, consequently the light will be more brilliant and burn for a shorter time than if it were directed upward. Whatever may have been stated at a public meeting, the wet collodion process is a slow one compared with the gelatine. As a rule, lantern slides by the wet collodion process are better than those made on gelatine unless the plates are specially prepared for the purpose. A large proportion of the commercial slides are made by the wet collodion process.

W. E. GRAY says: "I propose going with a party of friends for a few days to Paris at Easter. I thought of taking one of my cameras with me, and should feel greatly obliged if you could help me in the following matters in your 'Answers to Correspondents' column:—Is any permission necessary from the police or other Parisian authorities to photograph either landscapes, instantaneous views, or buildings, in or about Paris? Would the Customs House authorities offer any difficulty provided camera and slides were shown them, or would they want to open boxes of plates? Would it be advisable to label plate boxes with French labels stating contents?"—Permission is required to take photographs of the public buildings in and about Paris. If our correspondent is not familiar with Paris and its regulations as regards photographing there, he had better put himself in communication with the French Legation here, explaining what he wishes to do. In this way he may save himself what might otherwise be a considerable amount of trouble. If the contents of the boxes be politely explained to the Customs officials no difficulty will be experienced. Labels explaining the contents both in French and English should be affixed to the boxes containing the plates.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, April 6, will be *Portable Tents and Plate Changing Contrivances*. The Bank Holiday outing will be at Radlett. Trains from Moorgate-street and St. Pancras.

MR. J. TRAILL TAYLOR, of THE BRITISH JOURNAL OF PHOTOGRAPHY, is announced to read a paper on *Lenses* before the members of the Balloon Society at the Royal Aquarium on Friday, April 29. The chair will be taken by Mr. A. L. Henderson. Photographers are invited to be present and take part in the discussion.

A MEETING of those interested in the well-being of the Photographers' Benevolent Association, convened by Mr. J. Hubert, was held on Thursday, last week, Mr. William Bedford presiding. After hearing from Mr. Hubert a statement regarding an alleged grievance of a personal nature, and a proposal of the expediency of having an honorary instead of a paid Secretary, a motion expressive of entire confidence in the Committee of Management was proposed and carried by a large majority.

ON Thursday, March 24, the London and Provincial Photographic Association held a smoking concert, in place of the usual scientific meeting, at the Masonic Hall Tavern, City, London, under the presidency of Mr. J. J. Brighshaw. Upwards of two hundred persons were present. Among the singers and musicians were Messrs. H. T. Starnes, E. Mills, A. Glover, R. Keeves, F. W. Jones, George Leipold, P. Membrow, W. H. Ware, F. G. Read, J. Kitchener, H. G. Prim, J. Andrews, and L. Carozzi.

At the weekly meeting of the Balloon Society, held in the Royal Aquarium on Friday last, the following resolution was proposed by Mr. W. H. Le Fevre C.E., President of the Society, seconded by Sir John Bennett, supported by Mr. A. L. Henderson, and carried unanimously:—"That this meeting of the Balloon Society of Great Britain most cordially wishes Mr. W. K. Burton, C.E. one of its early members, health, prosperity, and safe return, on the occasion of his appointment as Engineer of the Imperial Institute of Tokio, Japan."

No. 1405. VOL. XXXIV.—APRIL 8, 1887.

THE PRESENT STATE OF THE STRIPPING FILM.

It is problematical whether at the termination of Mr. Wollaston's demonstration of stripping films at the meeting of the London and Provincial Photographic Association on Thursday, last week, there was one among the representative body of his hearers who did not go away imbued with the determination to give the process a trial when opportunity arose. "Easy as falling off a log," is a favourite Transatlantic standard of comparison; and this adequately represents the facility with which a seemingly difficult, if not mysterious, method of working was demonstrated in actual practice.

A sheet of paper which has been subjected for one or more seconds to an exposure in the camera—the precise time being quite unknown to the manipulator—is developed into a vigorous negative; the paper support is removed, and the negative is now found attached to a plate of glass; anon, the glass is removed in turn and the negative is found to be attached to a pliant and transparent support of flexible gelatine, capable of being rolled up for transmission by post if required—all these effected without a hitch, and by rapidly successive stages, indicate the state at which the stripping of films has now arrived. Surely the aspirations of those who desire the extreme of simplicity conjoined with the extreme in portability can scarcely farther go.

The paper prepared expressly for being subjected to the stripping-off treatment, possesses unmistakably a great advantage over ordinary negative paper, inasmuch as the negative may either be left in adhesion to the original paper support (the limit of the ordinary paper) or it may be transferred to a glass plate, or, finally, be placed in adhesion to a strong pliable sheet of gelatine. These advantages are so great that we may well express an unbelief as to any other negative paper being demanded in the future, especially as its preparation cannot be supposed to involve much if any additional expense, for it merely resolves itself into giving the paper a coat of size composed of plain soluble gelatine previous to applying the gelatine emulsion in which the negative itself is made. The negative, therefore, rests not upon the direct surface of the paper, but upon a substratum which is soluble in warm water and which forms an intermediary layer between the negative film and the paper support.

Of the precise constitution of this substratum we are not definitely informed, but there seems no doubt that a soluble gelatine possesses for this purpose qualities which render it specially valuable, because of its being unaffected by solutions or water at the ordinary temperature, while, when it is desired

that the negative be stripped, a brief immersion in warm water easily permits of the paper support being loosened from the negative film. Owing to this soluble substratum, if the negative is to be left on its paper support nothing is lost, while if it is desirable it should be removed everything is gained.

Let us suppose then that the negative has been developed, fixed, and washed, the next operation consists in removing it from the paper and transferring it to glass. While the negative is still wet it is laid face down upon a plate of glass prepared in the following manner:—After an application of powdered French chalk, which, after having been rubbed all over the surface is dusted off, the plate is coated with ordinary plain collodion, in which, by preference, one or two drops of castor oil per ounce have been dissolved in order to impart toughness. After this has set the plate is placed in a dish of water and rinsed until the removal of the alcohol and ether is shown by the surface being free from a certain apparent greasiness.

When this stage has been reached, the negative is "squeegeed" upon the plate, and the superfluous moisture is removed by blotting-paper. After a brief interval, but without giving it time to dry, the plate, with its adherent paper negative, is placed in warm water, which has the effect of dissolving the gelatine substratum, and permitting the paper to be stripped off, leaving the negative itself attached to the collodion film upon the glass.

But the collodion is in only slight adhesion to the glass, for it will be remembered that the surface of the latter received treatment with French chalk, or steatite, which imparts a certain degree of unctuousity to the glass.

The permanent support of the negative is a sheet of flexible gelatine, flexibility being imparted presumably by the addition of glycerine to the gelatine previous to its being formed into a sheet. When such a sheet is wetted and is rubbed in intimate contact with the negative film upon the glass, a close adhesion is engendered between the two, and after a little time, if the sheet of gelatine be stripped from the glass, it will be found that it has brought away with it the film, these two being ever afterwards united together.

The process, as we have just described it, may, perhaps, seem complex, and not unattended with risk, but, as a matter of fact, it is not only very simple throughout but also quite safe. To lose or destroy a negative in course of adopting the stripping operation is a thing practically unknown.

The method of stripping a negative film as we have described it has been, as a whole, patented by the Eastman Company, but no one will begrudge them their proprietary rights in the

patent if they will only ensure an adequate supply of the material being accessible to that section of the public who object to carrying a load of glass plates about with them when on a journey either for pleasure or business.

SOME POINTS OF PRACTICE IN THE USE OF ALKALINE DEVELOPERS.

We lately devoted some space to the consideration of the alleged uniformity of result to be obtained when using the fixed alkalies instead of ammonia with alkaline pyrogallol, and we think we showed the great danger there existed that a possible certainty and uniformity might become a probable uncertainty and irregularity from, firstly, confusion of nomenclature, and, secondly, impurity of the alkaline salt chosen. Before going further into our subject, we may emphasise and supplement our observations referred to by pointing out that the particular carbonate which appeared to us likely to obtain the ultimate preference—the carbonate of potash—is, further, liable to considerable variations of power owing to its deliquescent nature. Salts of tartar, the most common name for this carbonate, absorbs moisture from the atmosphere most rapidly and greedily; a portion of it left in a paper parcel, for example, would in a day or two run into a liquid, and, naturally, there would be all stages of moistures between absolute dryness and a saturated liquid, which would lead to as great irregularity as would be likely to occur with ammonia.

Hence we are led to the precautionary indication that both liquid ammonia and carbonate of potash should be carefully kept in well-stoppered bottles to avoid giving to, or taking from, the atmosphere. In this connection we may give a useful hint. The stoppered bottles containing strongly alkaline substances are, if left at rest for a while, very liable to become so fixed as to resist every effort at removal. But this mishap may be avoided by slightly smearing the stopper with vaseline, which will prevent the solvent action of any small particle imprisoned between stopper and neck. This little wrinkle is as useful as it is simple.

We do not know that in the results obtained by the various developers, and combinations of developers, ringing the changes on soda, potash, and ammonia, that any large proportion of workers claim for the fixed alkalies any superiority as to the quality of the negative produced by their aid. The chief point dwelt upon has been the volatility of the ammonia, and the consequent uncertainty as to its strength at any particular moment. Seeing that this liability to uncertainty of strength may be greatly mitigated by diluting the ammonia before taking it into the dark-room stock, we cannot but think that more has been made of this point than is necessary. It is as nothing compared with the quality of the image. But this is a subject that need not occupy us now; we may refer our readers to the indications of a long and laborious series of experiments made by us some time ago, and recorded in these pages.

So far we have dwelt upon the vagaries of the constituents of the alkaline developer before they are mixed together; still more pronounced, according to the advocates of soda and potash, do they appear when thus brought into use. A plate put into a soda or potash developer is exposed to a solution of uniform strength, they say, whether it take five minutes or an hour to develop, while with an ammonia developer it is impossible to say what amount there is present after the lapse of a few minutes. Taking the standpoint that we do of the

desirability of the utmost possible uniformity in the chemicals made use of, we admit this is a fair point to make; all the same, it must be said that the tendency of ammonia to escape from dilute solutions is very much weaker than with saturated solutions containing many hundred times their own volume of gas, and we must not lose sight of the possible absorption of carbonic acid gas by soda, &c. We may say that we have a series of experiments in view to ascertain the rate and extent to which weak aqueous solutions of ammonia part with the dissolved gas to the atmosphere at various temperatures.

We are naturally led from this branch of our subject to a consideration of the keeping powers of mixed developers stored ready for use in well stoppered bottles. These are used by many, and well spoken of; but a singular incident occurred in our own practice the other day, that has caused us to initiate an investigation, not yet concluded, in regard to it. We were developing a set of test exposures, and when repeating similar experiments of a fortnight previously, some mixed developers (soda and potash separately) failed to produce the same results. True, the stock of solutions was reduced in quantity, and scarcely did more than cover the bottom of the large bottles that contained them, and thus might have absorbed carbonic acid from the air, and so reduced their developing powers. Be the cause what it may—and we have not yet discovered it—the fact remains that in this particular instance the solution appeared to work differently a fortnight after it was mixed. Still we must say we have no grounds for anticipating that the explanation will be that ready-mixed developers do change.

The question of perhaps greatest interest to amateurs who are in the habit of developing large numbers of negatives at a time, is the length of time which the same trayful of solution will continue to act. We put the matter to a severe test last week (the temperature of our dark room was about 50° Fahr.). Undertaking some experiments involving a large number of developments, we arranged a series of trays with developers of gradually increasing strength, and passed each plate through each solution, beginning with the weakest (two grains pyro, eight grains sulphite, one minim of ammonia, half a grain bromide). Our developments lasted close upon two hours, and for the whole of that time the solutions were in constant use, and were only kept up to their original bulk, as the plates passing through absorbed the solution, by adding normal developer to them.

We were not testing the actual developing power of a particular solution, so that in our observation in this respect rigidity was not attempted. We may say that, practically, though upwards of a dozen plates were passed through the one solution, its developing power at the close of almost two hours' continuous work seemed very slightly impaired, the quality of the image produced not at all.

The development of a plate cannot be brought to the level of an exact science, for a "personal equation" must always intervene; still, the more facts that can be gathered to throw light upon the process the nearer shall we reach the goal of exactitude and reasonable certainty.

A PROPOSAL FOR A SENSITOMETER.

THE first defect in the instrument described last week, as actually constructed, is that for ordinary gelatine plates the exposure it gives is far too long. The maximum exposure given is, as stated, one-tenth of a second, the minimum, the one-thousandth. The latter would be brief enough for a camera

exposure, to be sure, but it must be remembered that in the sensitometer the exposure is made to direct light, a very different thing. Still, it might be imagined that if the period of exposure were really cut down to that figure, it would meet the requirements of even our most sensitive plates if due precautions were used to limit the quantity without interfering with the quality of the light employed.

But, as it turned out, such was not the case, and it may be at once stated that the theoretical measurements of time expected from the instrument were by no means worked up to, owing mainly to faulty construction. For instance, a plate giving 20 on the Warnerke sensitometer was exposed in the "drop" instrument at a distance of ten feet from the open door of the dark room, looking into another not over well lit apartment, and with no direct light from the windows entering or falling upon the sensitometer. The result was a rendering of the full length of the exposure slot, which after all, perhaps, would not have greatly surprised us had it not been that there was not the faintest sign of gradation in the tint, the limit of shortest exposure being as fully impressed as the longest. Recourse was then had to a feebler illumination, but still daylight, and the sliding shutter of the dark room window was utilised for the purpose. Several exposures were made with the shutter drawn out to varying distances, allowing a narrow slit or strip of white light to enter the room; but, even when this aperture was cut down to twenty inches by half an inch, and the exposure made at a distance of fourteen feet, the result was practically the same—a nearly even tint the full length of the exposure slot.

A little consideration suggested an explanation of the want of gradation. As we had been using the instrument, the base of the triangular opening in the exposing drop was lowermost, consequently the shortest divisions of the total exposure were made and finished first, or, in other words, when the shutter was gaining momentum as it gradually overcame its natural *vis inertiae*. Consequently, the shortest divisions of the scale, or those which ought to have represented a few thousands of a second, were subject to far greater error from friction and other causes than the longer ones, and as a matter of fact the gradation of the scale was very nearly neutralised. Upon making an exposure with the instrument reversed, that is to say, with the drop in such a position that the apex of the triangular opening commenced the exposure and the finer tints were made last, the difference was most marked; for, though the tint still extended the full length of the exposure slot, it was not, as previously, devoid of gradation, but, on the contrary, showed a gradually decreasing intensity of tint at one end of the scale. In this position, however, the instrument, if otherwise perfect, would be valueless in point of accuracy until the shape of the aperture was altered.

At the same time that the exposure was found to be too long for daylight, it proved to be altogether inadequate for artificial light, an exposure made at a distance of three feet from a small paraffine lamp failing entirely to produce any impression. Upon repeating the exposure at a distance of one foot a very faint image of a portion of the slit was obtained. When the front of the sensitometer was covered with a sheet of deep orange glass and exposed in feeble sunshine, the impression produced extended the full length of the slit; but when exposed, as before, in the dark room, the coloured glass was sufficiently powerful to arrest nearly the whole of the active rays.

From what has been said it will appear, then, that not

only is the instrument inaccurate in use from faults of construction, but it is also too limited in range for general purposes, giving too long an exposure under some conditions and not sufficiently long under others. But, in addition to these, there is one other circumstance that militates against the correctness of the readings, namely, the diffusion of the light along the exposing slit during the opening and closing of the shutter. As suggestions for overcoming these difficulties we offer the following:—

In order to minimise the effect of friction in arresting the free fall of the shutter, we would propose to considerably lengthen the latter, say, to three or four feet, allowing the greater portion of this to fall before the actual exposure commences. Thus, by the time the light commences to act upon the plate, the falling shutter will have acquired such a degree of momentum as to render it practically free from the interference of friction, provided, of course, that the apparatus is well and carefully constructed. Further than this, owing to the fact that the shutter will, after falling, say, three feet, drop through a greater space in a given time than when the exposure commences, as in the instrument constructed by us, after a fall of only two inches, it follows that with a given size of aperture a much wider range of exposure can be obtained, though, of course, the shape of the opening would have to be recalculated.

It is, however, questionable whether in the case of an opening at the upper end of a drop of the dimensions just named, the trouble of calculating the curve is necessary, or whether the nicety of theoretical accuracy is not neutralised by the mechanical faults of the instrument. A simple triangular opening, having for its longest side the distance the shutter is calculated to drop in a given time, would appear to us to be sufficiently near to accuracy to serve every purpose, the margin of error being well within that likely to occur from other causes, as, for instance, in development. With such an opening it would be a matter of the greatest ease to vary the size of the aperture at will, in order to suit light of different value or plates of different sensitiveness.

With regard to the alteration of the dimensions of the aperture, it should be borne in mind that as the readings are taken in terms of actual time no confusion or uncertainty need arise in adopting this course, provided the maximum exposure given by each aperture be calculated to bear a definite relation to each of the others. Thus, apertures giving maximum exposures of $\cdot 01$, $\cdot 05$, and $\cdot 1$ of a second may be divided on the same base line, and will bear the same definite relation to one another throughout. Thus, with the same drop, it may be rendered possible to deal with either day or artificial light.

In order to prevent the error arising from diffusion of the light in the direction of the exposing slit, we would insert between the drop and the sensitive film a perforated plate, forming a series of separate chambers, as in the Spurge actinometer. But, unlike the latter instrument, it would be unnecessary that the perforations be made of any definite sizes in order to admit varying quantities of light; all that would be needful would be to place a number of minute perforations at regular distances apart, the drop graduating the proportion of light admitted into each chamber so formed, and limiting its action to that particular portion of the sensitive film enclosed. The "tint" given by such an arrangement would, of course, instead of being continuous, consist of a series of isolated dots or fine lines, and these might easily be so arranged as to be self-explanatory in taking the readings.

Nothing has yet been said with regard to a standard of light, but the instrument was not originally intended as a standard, but merely for comparative purposes. If, however, a standard be desired of moderate reliability, probably nothing would prove more convenient than the reflected light of magnesium burnt at a given distance from a white screen of definite dimensions. Or it might be burnt at a fixed distance behind a translucent screen of small area, and the exposures made direct. The light given by burning magnesium sufficiently resembles that of the sun to render it a tolerably reliable guide for purposes of comparison, and it would certainly be under greater control so far as uniformity is concerned. It would also be easily applicable in connection with coloured screens, and for the direct comparison of white and coloured light.

We hope at a later date to be able to report upon the results obtained with an instrument we are having constructed on the lines now indicated; meanwhile, it is possible that improvements may suggest themselves to some of our readers interested; if so, we shall be glad to hear of them.

A LAWSUIT, and one which is likely to prove of considerable importance to the photographic profession, in reference to copyright and the protection of their works from piracy, is now pending in the Chancery Division of the High Court of Justice. As we announced last week, Mr. G. S. Paine, of Aylesbury, had obtained an interim injunction restraining another photographer and stationer in the same town—the former from reproducing, and the latter from selling copies of one of his photographs. On Friday last, an application was made to Mr. Justice Kay to extend the injunction until after the trial of the action. This the learned judge granted. This case will be watched with interest by more than those immediately interested.

PHOTOGRAPHY might advantageously be utilised by the Society for the Prevention of Cruelty to Animals. If some of the inspectors were supplied with a small camera, rapid lens, and instantaneous shutter, they could often secure a small negative which might, subsequently, and quickly, be enlarged on to bromide paper and produced in Court as evidence. A photograph of an overburdened and jaded horse, in the act of being cruelly ill-treated by its driver, would do more to secure a conviction for the offence than the exhibition of the animal after a night's rest and perhaps careful attention, an empty vehicle, and almost any amount of sworn evidence on the following day. How frequently, in the suburbs of London, is to be witnessed five or six great "hulking fellows" of the costermonger class, seated in a small vehicle behind a half-fed, diminutive "Jerusalem," while one of the number is unmercifully belabouring it with a heavy cudgel. In such a case as this an instantaneous photograph of the scene, if submitted to the magistrate, would, there is little doubt, frequently aid in the administration of justice to the delinquents. Several of the local Hon. Secretaries of this useful Society, we are given to understand, are expert amateur photographers, therefore they might well utilise their favourite art as an aid in the cause they so humanely espouse.

In connection with photography furthering the ends of justice, here is a suggestion by an ingenious friend, who, it is scarcely necessary to mention, is an enthusiast in photography. Much comment, as all are aware, has recently been made on the fact that policemen on duty in country districts, as was that courageous fellow at Finchley, are not provided with revolvers for their own protection. Our friend suggests, if the constables are not to be entrusted with these weapons, that they should at least be armed with syringes, or bulbs, charged with a solution of nitrate of silver. He says if that plucky fellow who has been so cruelly mutilated, could have discharged some silver solution on the faces of his assailants, the morning light would soon have developed them into conspicuous objects, and that no doubt ere this the miscreants would be under arrest. A man with a face

resembling those seen in some of the advertisements for Pears's soap, could not fail to attract considerable attention, and, if the suggested plan were adopted, excite suspicion. A nitrate of silver stain on the face, as all who have tried it are aware, is not easily removed by cyanide of potassium without injury to the skin, so that the remedy might prove worse than the disease. The idea of our friend for securing identity, though ingenious, is scarcely new, as we have heard of a photographer who always kept two or three small flasks of silver bath in his bedroom, ready to dash in the face of any nocturnal visitors he might encounter who had entered his premises surreptitiously in search of plunder.

THE preparation described last week for flattening backgrounds in oil colour is one of the best that can be employed for painting studio accessories. Balustrades, rockwork, and other movable properties painted with this material, will not show marks of handling or slight abrasions to anything like the same extent as they would with the ordinary turpentine flattening, or the distemper, so generally used. The surface may also, with care, be washed without causing injury.

It does seem somewhat anomalous, now that the more artistic section of photographers, in unison with the improved taste of the public, are aiming to make their productions, both as regards colour and style of mounting, resemble engravings as much as possible, that engravers and lithographers appear to be striving to make their work look as much like photographs as they can. Prints from typographic blocks and lithographs are now being largely produced in the recognised photographic brown colour, and the general "get up" of them is intended to convey the idea that they are veritable photographs. However, photographic artists may congratulate themselves that this class of work is chiefly confined to prints issued with some of the cheaper publications, and those used for advertising purposes.

WE have frequently directed attention to the more or less generally neglected state of photographic show-cases. The particular point we are now going to speak upon can scarcely, however, be called neglect, though it is so in one sense. We allude to the amount of moisture which is often imprisoned in, and which cannot escape from, the frame. The other day, on passing through Regent-street while the sun was shining, we noticed that in the majority of the frames exhibited, and indeed in some of the shop windows, the pictures could not be seen, owing to the condensation of moisture on the glass. Of course, when the glass became heated by the sun's rays, the water would again be vapourised and then condense on the pictures and mounts. Under these conditions the photographs are continually exposed in a humid atmosphere to a strong light. This is reckoned one of the most trying ordeals to which either silver prints or any other form of photograph can well be subjected. Hence, there need be little wonder that prints exposed to these conditions often show signs of premature decay. When a show-case is fitted up, if it is to be hermetically sealed, and it should be, care ought to be taken that the mounts and pictures, as well as the backboard, are made perfectly dry. To prevent ingress of moisture, the glass should be secured in the frame with putty, and the backboard painted with one or two coats of oil colour, Brunswick black, or other impervious material. When this is not done, it is better to have one or two small apertures in the top and the bottom of the case, so that it may be ventilated; then the moisture, as it becomes vapourised, can escape. In this case, a free current of air will probably exert a less baneful influence on the pictures than a continual humid atmosphere.

MR. BOUSFIELD, who recently brought orthochromatic photography before the Royal Microscopical Society, said he had employed these plates with growing satisfaction for some time. The objects represented were crystals of salicine displayed by polarised light, and the colours were purposely chosen to test as severely as possible—and a more exacting test could not be chosen—the capacity of the plates used. He found all to fail at the red end of the spectrum.

DR. CROOKSHANK's exhibit was intended to show the teaching value of photo-micrographs, and consisted of enlargements on bromide paper

from negatives taken with the microscope, the objects being the flagellated protozoa in the blood. The amplification was seventeen hundred and fifty diameters, yet markings and histological details of great fineness were clearly portrayed.

THE photographs taken by the aid of the new apochromatic lenses showed the results of the combined action of both new objective and eye-piece. The actual photographs on view were not considered of very great excellence, but as exhibiting the power of the optical combinations were looked upon as most satisfactory.

It is expected that, socially, the Manchester meeting of the British Association will be one of the most brilliant ever held. A very large sum has already been subscribed, and liberal arrangements are being made for excursions and other entertainments. Sir Henry Roscoe, it will be remembered, is the President.

BICHROMATED GELATINE EMULSION PAPER.

FOR the benefit of those who desire to try this method of printing with tissue or paper free from the difficulties which attend the commercial papers not specially prepared for the purpose, I will give the latest formula I have employed for the emulsion, premising that it is reduced to such a degree of simplicity and requires so little precaution in the matter of light during preparation, as compared with rapid emulsion for plate work, that any one can prepare it in an ordinary room and with full gaslight.

The requirements are a tolerably thick and perfectly soluble film of gelatine holding incorporated with it a minimum of silver salt, though, of course, the proportion of the latter will vary with the purpose to which the tissue is to be put. For positives on opal, or for transparencies, the quantity must be very small, but for the reproduction of negatives, especially for line work, a larger proportion may be used. The quality of the gelatine is of the utmost importance, and those samples which are held in the highest estimation for ordinary emulsion purposes are the ones to be carefully avoided for this. The so-called "hard" gelatines, in the preparation of which alum in some form or other is employed, are quite unsuitable, owing to the fact that the mere contact with potassium bichromate serves to render them more or less insoluble without exposure to light. In some cases the insolubility is complete, while in others, though only partial, the development requires the use of such hot water that all the finer gradations of the picture are lost. Nelson's "No. 1 Photographic" is an admirable brand for this and similar purposes, or a cheaper kind of the same makers known as "No. 1 Flake" is equally good if carefully filtered to free it from mechanical impurities.

In order to simplify, as far as possible, the manipulations necessary in making the emulsion, I have adopted Monckhoven's system of first converting the silver nitrate into carbonate, and then, after washing the precipitate to free it from soluble salts, incorporating it with the gelatine, afterwards converting it into chloride or bromide. This gives, without the trouble of washing the emulsion itself—always a tedious operation—a preparation free from the usual decomposition salts, though, when the emulsion is to be applied to paper, this is of less importance than is the case with glass, since the paper absorbs the salts and prevents, in a great measure, their surface crystallisation.

The formula stands as follows:—

Nelson's No. 1 gelatine	600 grains.
Nitrate of silver	70 "
Chloride of ammonium	20 "
Bichromate of potash	150 to 200 "
Carbonate of soda.....	9 s.
Water	to make 10 ounces.

First dissolve sixty grains of the nitrate of silver in a small quantity of water, and throw it down by means of about an equal weight of carbonate of soda, also dissolved in water. Allow the precipitate to settle, and decant the supernatant fluid once or twice, and finally drain closely. Let the gelatine be swelled thoroughly in cold water, and when the carbonate of silver is washed add to it a small proportion of the gelatine—say, one-fourth or one-sixth; apply heat, and when dis-

solved make up the quantity of emulsion to six ounces. Next add the chloride of ammonium, and stir well until dissolved, and at this stage, or later, the remaining ten grains of silver nitrate can be added and also stirred until dissolved. Place the whole in a warm place for an hour or so, or immerse for a shorter time in a saucepan of very hot or boiling water; finally, add the remainder of the gelatine and the bichromate of potash, and make up the total quantity of emulsion to ten ounces.

The resulting preparation will be of a deep red colour, owing to the presence of chromate of silver, which serves to render the tissue more opaque to light. It will be noticed that I do not employ hydrochloric acid to convert the carbonate of silver as would be done in Monckhoven's method; I thus avoid the inconvenient effervescence caused by the acid, and the carbonate of ammonia formed is afterwards decomposed more gently by the bichromate of potash. The emulsion, as will be seen, is very strong in gelatine, containing sixty grains to each ounce. This enables a good stout film to be applied to paper by simply floating, and the layer sets and dries rapidly, owing to the comparatively small proportion of water it contains.

Almost any sort of moderately smooth paper will answer the purpose for this process, as it only acts as a temporary support. It must, however, be a paper which, from its sizing, expands readily and evenly under the influence of moisture. Some papers partially sized with resin prove very refractory in this respect, refusing to lie flat when coated with warm emulsion, even though thoroughly wetted previously. Such must, of course, be avoided. Common wove note paper answers very well, as also does pretty good quality printing paper; the latter from its porosity separating from the picture on development with great ease. As an instance of the little care necessary in the selection of the paper, I have produced a print from a piece of tissue made on printed newspaper.

Coat the paper by floating for a minute on the emulsion, then adroitly draw off the sheet, and quickly lay it on its back on a level piece of blotting-paper until set, then hang up to dry.

H. Y. E. COTESWORTH.

ON THE USE OF THE STEREOSCOPE AND ITS SCIENTIFIC APPLICATION.

II.

IN applying the stereoscope to purposes of scientific investigation, it will be necessary for the observer to possess a good instrument of suitable pattern, to cultivate his powers of perceiving, by its means, the effect of solidity or third dimension of space as presented on the union of its two plane but dissimilar pictures, and to thoroughly understand the principle of the physiology of vision whereby the idea of solidity is produced in the mind.

In making choice of an instrument for normal vision with eyes of equal power, it would be well to select one of the lenticular form fitted with eye-pieces containing achromatised, prismatic, or whole lenses of about five inches focus, and mechanical contrivances for focussing and separating them to enable the sight to be exactly suited to the slightly varying circumstance arising in practice. For eyes of unequal power, or possessing other peculiarities not fatal to successful binocular vision, the mechanical features of the instrument might be similar if the powers of the optician, to suit the special requirements of the case were not limited thereby. It need scarcely be added that every advantage should be taken for optical skill to promote success, and make matters comfortable to the observer. It may be necessary to make modifications in the design of the instrument to admit of the examination of slides of unusual shape; but as these can only be settled when the necessity arises, it would be out of place to venture upon giving details here.

To cultivate the sight to ensure its possessing the requisite keenness and delicacy for noting the small variations in the amount of separation of parts of the same objects in the two halves of a binocular slide, and of seeing these alterations as differences of distance or as solidity, some simple drawing should be made like those that were supplied as slides when the stereoscope was first invented, and which usually illustrate articles on the subject. They consist principally of unsymmetrical geometric figures produced in pairs which, on being

viewed in various positions in respect of each other, as both placed the same way, or with their left or right sides to the centre, present the appearance of plane, raised, or hollow objects. Mere lines if not truly parallel are good exercises. These appear to extend from the observer into space either from the top or bottom of the slide, as their amount of separation is least at the one point or the other. The eyes, in travelling up such a pair of lines, and uniting them into a single one, must alter the convergence of their optic axes at every instant, exactly in the same way as when solid natural objects are viewed, the mind in both cases interpreting the changes of convergence as variations of distance. It will be gathered from these remarks, that any lines or points that may happen to be slightly displaced in respect of others will call upon the eyes to make this effort, and produce the corresponding idea in the mind that is to locate them in another plane in space nearer or farther, or their displacement makes them less or more widely separated.

Among the scientific uses of the stereoscope may be mentioned the well-known one of detecting forgeries of notes or enques, because it is utterly impossible to copy or touch up a plate by hand sufficiently accurate to pass this test. It may be done well enough to deceive the unassisted eye. Let, however, the spurious and genuine notes be examined together, in the stereoscope, and their total unlikeness will be at once apparent, for their lines and figures instead of appearing in one plane will undulate to and from the observer in a ridiculous manner and immediately proclaim their origin. It would require a delicate and powerful micrometer to prove a difference that may be immediately made manifest in the stereoscope.

Some years ago the instrument furnished a very beautiful ocular proof of the spherical shape of the moon in Mr. De la Rue's photographs of that orb taken at different periods of her libration. In those arranged as binocular pictures which I had the pleasure of handling, the periods of libration seemed to have been slightly too far apart, the consequence being that the moon appeared more like half of an elliptical body viewed endwise instead of as a hemisphere. Another attempt (I believe it was so intended, for there was nothing to warn a visitor that it was not) to prove an astronomical fact was exhibited at the South Kensington "Loan Collection of Scientific Apparatus" among the photographs of a then recent total solar eclipse. In this case the slide was supposed to show the image of the dark body of the moon some distance in front of that of the sun, the effect having been produced by taking the pair of photographs composing the slide with a short interval of time between. The representation conveyed what happens to be fact, but the way in which it was produced was totally false and unscientific, proving nothing. The same illusion would have arisen had the sun and moon been mere discs sliding over one another in actual contact. To my thinking it was quite out of place in a scientific collection even as a curiosity, unless it were accompanied by an explanation.

One of the new (at any rate new to me) uses of the instrument I wish to suggest is in connection with photographic star mapping and the detection of motion or change of place of any individual star in respect of its fellows, by the comparison of two photographs of the same quarter of the sky taken at two different periods, the interval of time being long or short as the necessities of the case and practice may suggest. When two such photographs are viewed in the stereoscope all objects which had been what we usually call "fixed" would appear in one plane, while any that had moved during the interval between the dates of the photographs be they planets, planetoids, or comets, would stand out, as it were, in another. The plan, it appears to me, would be of much value if only as a rough-and-ready method of picking up objects possessed of their own proper motion for verification and study with the circles in the usual manner. It would also be some safeguard against reckoning defects as celestial objects if successive exposures were not made. The pair of maps would have to be examined in two ways upright, or let us say in the position they were taken for the detection of motion in right ascension, and then each turned round a quarter in the same direction to make evident any movement in declination.

As an aid to spectroscopic research, it is probable that the stereoscope might prove very valuable and reveal many new facts in making the comparison of spectra under various physical influences much more easy and certain than at present. A binocular spectroscope

would serve better for purposes of direct observation, but of course would be of no use for dealing with photographic records and no better than a single one for producing them. I am not aware whether such an instrument has been made, and as it does not appear to me that the difficulties of constructing one are insuperable, I mention it in conjunction with binocular slides and stereoscope, because I feel sure there is a field for both. Here is an instance in which either method would be of use. One of the problems connected with the spectrum of the sun is to settle which of its lines are due to the absorption of its own gaseous envelope and which may be set down to the contents of our atmosphere. To separate these two series M. Cornu suggests a plan whereby he takes advantage of the effect on the lines of the sun's revolution on its axis. As the lines (due to the absorption of his gas) on the spectrum of the advancing limb of the sun are for a well-known reason displaced towards one end of it and those of the same kind in that of the receding limb towards the other, while those produced by atmospheric absorption are not affected by the sun's motion but remain stationary, the spectra of these two portions when viewed alternately, but in rapid succession, will exhibit the lines in two series, one set appearing to flicker or tremble the other not. If two photographs of the solar spectrum were taken under these conditions and subjected to the stereoscopic test, the lines produced by the causes in question would be separated into two distinct planes of distance, capable of being leisurely studied and compared with the spectra of bodies produced by the electric arc or other suitable means. The photographs might be made in sections of any length, because it is easy to modify the stereoscope to admit of their being passed under review parallel to one another, the one for the off eye being started and kept two inches or so in advance of the other. I fancy I have described a stereoscope in these columns for panoramic slides that would be admirably suited to long photographs of the above kind.

I hope I have given a sufficient reason why the stereoscope should not be consigned to oblivion, but that as a scientific instrument for use by intelligent men it has a future before it nobler and more lasting than its day as a mere caprice of fashion.

JOHN HARMER.

ACCESSORIES OF THE LANTERN.

CHAPTER V.—SCREENS IN LARGE HALLS, &c.

In the preceding chapter (page 182) was described a set of eight screen poles, each four and a half feet long and one and a half inches in diameter, fitting together in fishing-rod fashion, so as to form two uprights capable of supporting a fifteen or eighteen-foot screen. The two upper rods of each upright may be of light wood, such as deal, but the lower rods, having more strain put on them when in use, are best made of a tough wood—oak, for instance. If they are made a quarter or half an inch larger in diameter deal may be used for all the rods.

Similar sets of uprights for screens of ten or twelve feet square may be cheaply made by using the common broom-handles, which are sold ready painted at about fourpence apiece. It is an easy matter to fix on the end of each a tin or brass tube five inches long, so that they will join together like a fishing rod. The rods or handles being about four feet long, three joined together will make a twelve-foot upright, and two of these uprights raised on chairs, if necessary, will support a small screen. They are not suitable for a fifteen-foot screen, as they bend to an alarming extent if more than three rods are joined together.

The way these uprights are used is as follows:—A rope or cord being procured about twenty yards long, the upper corners of the sheet are tied to the middle of the rope with tape or twine in such a manner that the stretching of the rope will fully stretch the top border of the screen; the sheet may be also tied to the rope at one or two places between the two corners, or, what is perhaps better, the rope may have been previously threaded through a couple of the eyelet holes. The upper border of the screen being thus attached to the rope, the next proceeding is to tie the cord to the summit of each upright, in which an iron screw-ring has been fixed, a distance being allowed between the poles and the corners of the screen of about three inches. The uprights, with the screen attached, are now raised to

the vertical position and separated the required distance, the two ends of the long rope are then drawn diagonally right and left respectively and attached to screw-eyes inserted in the floor at a few feet from the screen. This stretches the upper part of the sheet nicely; the lower corners may be drawn taut by means of cords attached to two extra screw-eyes in the floor. The screen, being now stretched at each corner, should be nearly free from creases; two or three extra cords tied to the eyelet holes where required will render it quite flat and even.

In large towns there are usually one or more halls of such size that ordinary screens erected in them appear quite lost in the immensity of space. A twenty-five feet screen is not too large for a hall one hundred and fifty feet long and sixty in height and width. When a hall of this calibre has to be dealt with there are, as a rule, special facilities for rigging up a large sheet; this is very fortunate, as it does away with the need of large and cumbersome screen poles, which, being too heavy for small screens, would be rarely used. The facilities referred to are the holes that are left in the lofty ceiling for ventilation and other purposes. Through two of these holes situated over the spot where the screen is to be, ropes may be let down to the floor; the operator below then fixes on the end of each a small pulley block through which a long rope is rove; the pulley is then hoisted up to the height of about thirty-five feet above the floor and the rope is made fast above. The cords which have been rove through the pulleys are then attached to the upper corners of the large screen, which may then be hoisted up by the pulley ropes and stretched taut in the same manner as when the wood uprights were used. In this way a large screen may be easily stretched by two persons in half an hour.

It will be observed that somebody has to climb up to the space between the ceiling of the hall and the external roof; this person is generally the hall porter, who does not at all like the ascending business. At a certain hall the porter said it was "worse than purgatory." He did not state how he obtained the special knowledge which enabled him to make the comparison, but a half-crown induced him to go through the ordeal. Excusing himself for a few moments, he presently appeared in a suit which was not his best, and then went aloft and fixed the ropes. After half an hour's work he descended, having apparently been luxuriating in a bath of soot, which rendered it needful for him to go home to readjust his toilet.

Lecturers nowadays so frequently employ the lantern to illustrate their discourses and to increase public interest therein, that in "lecture sessions," consisting of entertainments on a dozen different evenings, it is not uncommon for nearly half of them to be lantern lectures. There is consequently a tendency to make special provision for erecting screens in halls where they are often required, and, as this can be done at very small cost and trouble, it would be well if every hall were so fitted. All that is required is a small pulley permanently fixed at a suitable height on each side of the room; the best place in halls of moderate width is on the upper edge of the cornice. In wide halls, in which the screen can be placed close to the wall behind the platform, the pulleys may be fixed on this wall. The distance the pulleys are apart should be about equal to their height above the floor, and will depend upon the size of the hall; twenty feet would suffice for a hall sixty feet long requiring a fifteen-feet screen. The pulleys should each have a rope rove through long enough for the two ends to reach nearly to the floor. A small weight may be permanently tied to the end of each cord, so that if a rope end is accidentally drawn up out of reach the weight will bring it down again. When a screen has to be stretched, one end of each rope is tied to the top corners of the sheet, which is then hauled up by drawing on the opposite ends of the ropes. This method is perhaps as expeditious and convenient as can be devised; a sheet of any ordinary dimensions may be fixed up in this way in a few minutes.

When a lanternist arrives at a hall with his apparatus he usually begins operations by fixing up the screen; when this is accomplished he turns to his biunial and has to find out the right place to put it so that the image will nearly cover the screen. If he guesses, the chances are that he is a few feet too near or distant, and when the hall keeper has surrounded the apparatus with long, heavy forms it is not a very easy matter to alter the position afterwards. Hence it is a good plan to measure off the distance of the lantern from the screen with a long

tape measure, having previously ascertained the required length; but a more convenient and equally effective plan, which does not require one to remember the exact number of feet needed for each size of disc, is to use a distance meter. This can be made in the simplest way by means of a piece of wood ten or twelve inches long and three-quarters of an inch square; to the centre of this tie firmly the end of a cord or narrow tape a yard long. The final adjustment is made during an exhibition of the lantern on a disc of the usual dimensions. A slide with an ordinary circular mat being inserted in the lantern and its image thrown on the screen, the operator takes his stand close by the front lenses of the lantern, then holding the tape just under one eye and touching the skin with one hand, and holding the stick in the other hand in a horizontal position and parallel with the screen, he looks towards the disc with one eye closed, moving the stick between his open eye and the screen until it visually just covers the diameter of the disc; the space between the stick and the eye of the observer, probably about two feet, is then noted by means of the tape, which is knotted at that distance. Our simple distance meter is now ready for use in the next exhibition. The screen, which need not be of the same size as the one used in the adjustment, being duly stretched, the operator stands in the middle of the hall, and holding the knot in the tape in contact with the skin just under the eye he prefers to keep open, he holds the stick as before between his eye and the screen at such a distance that the tape is made taut, he will then notice how much of the width of the screen is covered by the stick; this being the diameter of the disc that would be shown at that distance, he will at once see if it is correct, if not he has only to advance or retire till he finds the right place to put the lantern.

This distance meter will suffice for any ordinary size disc with the particular focus lenses which were in use during its adjustment; if another set of lenses is used it will be necessary to readjust it, and to make an extra mark or knot in the tape for use with these lenses.

ALBERT WM. SCOTT.

PORTABLE DARK TENTS.

THERE is very little doubt that the "box" form of tent, such as is now in general use, is the best that could be devised. Rival forms are few and by no means formidable competitors from the point of view of general utility. The "umbrella" (both for changing and development) is obviously open to many grave objections which it would perhaps be invidious to enumerate, while the changing box that compels the operator to handle his plates per a pair of armholes, and watch his movements through a pane of ruby glass, possesses what, to the writer, appears a fatal defect in interposing a barrier between the visual orb and its objective. In transferring an exposed plate from the dark slide to a light-tight receptacle pending development, only a very slight amount of skill would be necessary; but in taking an unexposed plate from its original package and putting it into the slide, considerable uncertainty would exist in the average mind as to whether it had been turned right side out or not. This is surely a big nail in the coffin of the "armhole" changing box, for the presence of the least qualm in connection with such an important matter destroys at once whatever other useful characteristics the well intentioned piece of apparatus may possess.

Accepting then the box type of developing tent as the standard, and on the whole the most desirable for the purpose, one's remarks will necessarily be held as referring exclusively to it when dealing with the subject indicated by the title at the head of this article. Throughout the trade the words dark tent are taken to imply a similar concrete meaning. This points to the view that a consensus of experts are agreed upon the principle that what is, is best, in regard to the dark tent. Exception cannot readily be taken to this; it is only upon matters of detail that a fair quarrel can be picked with the makers. Some very peculiar notions as to the amount of space essential to the operations of development are in vogue amongst them. I have before maintained that anything under a 10×8 tent is practically useless. One made to this size permits elbow movement within a space two feet four inches by one foot seven inches; little enough in all conscience. One maker, however, thinks this a prodigal waste, for he offers us a tent which, though blessed with most exemplary qualities in the way of what reads like phenomenal portability and lightness, is utterly spoilt by the paucity of movement it allows; for I submit that a working space of eighteen inches by twelve is totally inadequate. True the flexible adjunct is said to increase that space to thirty-three and forty-eight inches respectively, but be it remarked,

only when extended on a table. Such a tent, however serviceable in a room, would be of little use in the open air, or on the deck of a ship, or, indeed, in any outdoor situation. My ideal tent is one that could be laid under contribution either in or out of doors impartially.

Elbow-room and plenty of it is always necessary when developing. So, too, is water. The method of providing a reservoir of this indispensable fluid is usually crude, and never satisfactory. A small tank, with a hole in the bottom, is placed on the top of the tent when open, over another hole, and the supply is obtained and regulated by a piece of rubber tubing and our old friend the American water-clip. I could never understand why this tank—flatter, of course, but of increased area—should not be fixed inside the tent. It might be supplied as now from the outside, and controlled inside by a small tap—a neater and handier arrangement than the tube and clip from all points of sight. I understand that some such improvisation has been adopted by one maker. In regard to shelf accommodation, our tent is, as a rule, rather too generously treated. This is the age of concentrated developers and percentage solutions, and all that is needed for the bottles is a small ledge with a thin wire rail to hold them in their places. Space might thereby be economised and weight avoided. Turning to the sink, little more than sufficient outlet for six ounces of liquid is needed, whilst it seems to me that the flexible tray might be dispensed with altogether, and a double frame, made to size, which, when clamped, makes the plate to be developed form its own bottom, substituted for it.

The question of ventilation in this connection is what Mr. Swiveller would term "a staggerer," for, at every turn, we are confronted by our old enemy, or friend, light. In my opinion, the current should come neither from the top, where, so far as I can discover, no attempt has, as yet, been made to improvise a method of ventilation, nor from the base, where, in one case, a small arrangement upon the fan principle has been tried with equivocal success, but from the sides, which at present, in most tents, are flexible. As before stated, the twill composing them is generally triplicated; if this were judiciously perforated at the opposite extremities of both sides of the tent, I think it would be found that some relief had been obtained from the intolerable stuffiness so much complained of now. More, if carefully done there need be no fear on the score of light. I believe this, or a similar dodge, has lately been adopted by one or two amateur workers.

Mr. John Morley recently prophesied the imminence of a quiet time in literature: I am bold enough to apply the rational effort of the ex-Chief Secretary to photography, and to predict a sort of comparative *dolce far niente* throughout its domain for some time to come. It would be well, I think, if under such conditions a little of the feverish craving for chops and changes, which has characterised both sections of the craft during recent years, were turned in the direction of such neglected items—"without which no outfit is considered complete"—as the portable dark tent and other things of no pertinence to the present occasion. Cameras made for use with the wet process are no longer seriously thought of in connection with its dry successors, nor should portable developing tents originated under the first set of circumstances be any longer admissible under the second; the two cases are exactly parallel. The directions in which it is essential that the eye of the improver must turn, are—admitting that the form of the present tent is to be retained—that of a decrease of weight, readier susceptibility to external manipulation and internal convenience, and adaptability to modern needs. As I have before pointed out, substitutes for wood and twill are obtained easily enough, whilst if but a fraction of the ingenuity that is at present lavished upon far less important things were diverted to the emendation of the mere details of our tent, something really useful would, I am convinced, result. The matter is simply one of a little enterprise; the rest is all plain sailing and excellent profits.

MARSTON MOORE.

SPECIMENS OF WORK.

EVER since photography became a recognised art or profession, it has gradually become a growing custom for employers, when advertising for assistants, to insert a clause in their advertisement requesting the applicant to forward samples or specimens of his own work, whether in operating, printing, or retouching; and the question of the wisdom or otherwise of this system, though ever and again, and that at very short intervals, cropping up in the correspondence columns of this and kindred journals, has never yet, to my knowledge, been either fully ventilated or discussed. Operators who have complied with the request, and forwarded specimens of their work to an advertiser, have often complained of the delay that has occurred prior to their return; and in many cases the complaint has gone farther, it has, in fact, been alleged that when returned they have been in such a state as to be practically unfit to show again; and sometimes I have heard

operators, printers, and retouchers bitterly inveigh against the specimen system, because they had sent the only samples of their work that they possessed, which had never been returned at all, thus leaving them in a position utterly unable to comply with a similar request from another, and probably more honourable, source. Of course I am perfectly aware of the fact that no photographer of any standing, or with true feeling for his fellows, would wilfully detain for an hour more than necessary the specimens submitted to him by any applicant for work at his establishment. But pressure of other business matters, far more important to him, may, in many cases, cause the return of specimens of work to be overlooked or delayed for a time, or they may be kept back in case some other applicant who is being first attended to might not prove all that is required; and in either case the result is the same, the owner and producer of the detained samples has to allow some other vacancy to be filled, because, without his specimens, he does not care to apply for the berth.

One of the first and most important questions that occurs to me, and having a full and direct bearing on the whole question as to the wisdom of the system of sending specimens or asking for them, is how and when are *employés* to obtain the same? When a photographic assistant, be he operator, retoucher, printer, or all-round hand, is in what appears for the time being to be a perfectly comfortable and permanent berth, he is not apt to let thoughts of a possible and probable dark-to-morrow, when he shall be added to the already far too numerous list of the unemployed, in any way disturb his present feeling of equanimity and satisfaction; and even if he were, he would not, under the circumstances of the case, feel himself justified in asking his employer to allow him to have specimens of his work, indeed the very fact of asking for anything of the kind would be calculated to raise thoughts in the mind of even a moderately suspicious mortal (and photographers, be they employers or employed, are still but human) as to whether his assistant was not, after all, dissatisfied with his position and on the look out for another berth. Then, again, when a rupture has actually occurred, and the assistant is either under orders to leave or has himself given notice, even if he obtain permission to have for himself a few specimens, either by purchase or as a gift, it is not always an easy matter to obtain prints of the special subjects he wishes for, or even to remember the subjects themselves which would be the most suitable for the purpose he requires. Then there are employers, even in our own beloved profession, who are not all they might be as men, and who would flatly refuse to allow the operator or other assistant to have any specimens at all, in which case he must either stoop to dishonesty (perhaps, in this case a rather harsh term) and obtain them without asking, or he must state his case truly when applying for another situation, which would in many instances prejudice his chance of being the selected applicant; or a third course is open to him, he can obtain, by purchase, specimens of work, which he may be quite capable of equaling, or even excelling, but which are, nevertheless, no more specimens of *his own work* than if they were far superior to anything he might himself be able to produce. He may carefully select these, sending only such samples as may in every respect resemble his own work, as to lighting, posing, and general character, but still we cannot get away from the fact that he is literally and positively *not* the producer. Such a man would possibly fail to see anything dishonest or wrong in what he had done, he would probably bring to his assistance such casuistry as the following: "Specimens are asked of work that I can produce, and the specimens I am sending are such that I can equal, or even excel, at any time, therefore I am acting in a perfectly honorable manner." Argument of this sort notwithstanding, the fact remains, the plain, unvarnished fact, that those specimens are not his own work.

Passing by, for a time, the question of the difficulty or ease of obtaining genuine specimens of one's own *bona fide* work, we come to the question of the wisdom or advisability of submitting such specimens once they are obtained. There is no doubt whatever that there do exist certain dishonest individuals who make a practice of filling their show-cases with photographs not their own, and that to obtain these they do not scruple to stoop to very low means. Though if so designed, they can purchase any number of photographs that would answer their purpose, they often prefer to insert an advertisement for an assistant and require to see specimens; such specimens once sent are never seen again by the sender unless he happens to personally visit the advertiser with a view to obtaining their restitution, and then he probably discovers them being utilised as specimens of this man's *own* work. True, no decent photographer would act in such a dirty manner; but how, I would ask, is an assistant in want of a berth to know who and what an advertiser may be, more especially if he gives an address at a distance, or to initials, or an assumed name, or pseudonym at a false address? He has lost his specimens, and he cannot obtain more. What is he to do?

So much, at present, for the assistants' side of the matter; now for the employers. What security or proof has he that the specimens submitted to him are the genuine work of the applicant? He has only the bare word of that applicant himself, who may be a purely honorable man, who would not deign to stoop to dishonesty, or he may be the very contrary. He is at any rate an entire stranger, and the would-be employer is therefore utterly unable to judge of his *bonâ fides*. Such being the case, who shall say that the system of requesting and submitting specimens is in any way a wise one? For my own part I can look upon it in no other light than as a mere farce, one of those particles of red-tapeism that cling to most business transactions, and which requires only a vigorous onslaught and a free and impartial discussion to cut it away bodily and to render it a thing of the past.

It may be asked, if we do away with the specimen system, how are employers to judge whether the style or quality of an applicant's work are likely to be suitable for them? and this query may, I think, be readily answered. Why not make it a rule to adopt as a system, as in other professions and business, a term of probation or trial. I do not think that an assistant would, as a rule, object to go to a situation for a month's trial to see if he suited the employer, and the berth suited him; in fact, I believe it is even now the custom in some houses to do this, although specimens of work may have been first submitted, and I would contend that it would be much better for it to be done generally, as a substitute for the submittal of specimens. Taken shortly, the matter comes to this, an assistant is engaged after specimens of his work have been seen, and if he is not suitable, he does not even then stay, as a rule, more than a month, and he then considers himself aggrieved, as after his specimens having been approved, he himself is not; owing to the fact that a few selected specimens, however good, of any man's work, never can give a criterion as to his ordinary work either as to general quality or method of production. The specimens may be really first class as obtained in one studio, but on transference to another their producer may be utterly unable to produce anything to equal them, or his method of work may be found to clash severely with the method approved by his new employer. In such a case as this, it is the employer who considers himself the aggrieved person.

The month's trial would, to a great extent, obviate this kind of thing. The employer would, before engaging for that month, have heard from his new assistant's former employer what he considered his work to be, and he would further have, possibly, found out what was the general quality of the work issued from that studio which would undoubtedly be far more satisfactory than the submittal of any number or any quality of specimens, about the *bonâ fides* of which there might be some lingering doubt, possibly quite undeserved.

The general quality of the work issued by an applicant's former employer, when he has held the situation for any space of time, would be to my mind, and possibly to that of most people, by far the best criterion by which to judge his abilities. That work might not perhaps be exactly in the style or even of the quality which I should require, but still it would be sure to display certain characteristics which would show, to my mind, whether the applicant was likely to prove a suitable assistant to me. Personally, such being the case, I should engage him, and after the first month I should be able to see whether or no I had been mistaken. I say after the first month advisedly, as I do not consider an assistant can always fall into the working of any one particular studio in a day or a week, and if a little time is required better give that little time than change again and have to give it after all to some one else.

In short my whole argument is this, that the present system of sending specimens of work by photographic assistants is an utterly unsound one, and founded on perfectly erroneous bases.

C. BRANGWIN BARNES.

SULPHURATION OF PRINTS.

I do not propose to enter into the discussion as to the relative permanence of platinotype and silver bromide prints so much as to call attention to some points which, if overlooked, might be the cause of valuable processes being condemned in the future.

The first point that strikes me is that, if we are not careful, after Mr. Gifford's interesting experiments his tests upon the Eastman paper will get to be taken as representative of the permanence of any printing process in which the image is formed, or, rather, supposed to be formed, by the development of silver bromide. I say supposed, because we must remember that the way the Eastman paper is prepared is a trade secret, and there are several other papers in the market, each having distinct characteristics peculiar to itself.

Any one who has experimented at all in the preparation of silver bromide paper, I think, will agree with me that silver bromide alone will not give all the results which can be obtained with the papers supplied by the various makers. Therefore it ought to be a point clearly understood by photographers that because the Eastman paper came so satisfactorily out of the severe tests it was put to in the hands of Mr. Pringle and Mr. Gifford, it does not follow that all bromide papers will stand the same tests or would be equally permanent.

The degree of permanency of any print depends upon the least stable of the constituents of which it is formed, and it is of little use arguing on the basis that in the one case we have metallic silver only and in the other nothing but pure platinum, if all the time the images on the bromide paper consists of silver *plus* other unknown substances added to obtain a more pleasing colour, or if the platinum forms some chemical combination with the sizing of the paper to cause the deterioration of the print. One of the subjects in the late discussion was whether the paper itself is not part of the print, and I think that Mr. Pringle was quite right in speaking of it as such. In a photograph the depth of tone of the paper must be nearly as important as the deposit upon it.

However indestructible the substance on the paper forming the image may be, if any chemical compound has been formed in the paper support, which in time is the cause of destroying the purity of the colour of that paper, we speak of the print as having faded because the darkening of the whites and half tones have made the deep shadows appear by contrast less dense. I take it, that in speaking of a permanent photograph we mean that the range of tone between the purest white and densest black have been preserved to the same extent as when the photograph was first produced.

I can hardly gather from the sentence in Mr. Berkeley's article, "Let the statement go forth that some or many suppose that reduced silver prints will prove more lasting than the albumenised ones," whether that gentleman means to contend that the many are wrong.

If in any of the gelatino-bromide papers in the market there is any organic compound of silver added to the silver bromide to alter the colour of the image, then I should be afraid of them fading, but if they only consisted of silver bromide I do not think after development that we need fear the sulphuration of the metallic silver in ordinary atmospheres. Sulphide of silver is supposed to be about as permanent a silver compound as any.

Of course in albumenised paper we have an organic silver compound which rapidly fades under the sulphuretted hydrogen test, and in the case of the old development printing processes the papers were floated on a nitrate of silver bath, and in consequence we would still have organic silver compounds; but even then it was found that the developed prints as a rule stood better than the printed out ones.

But now I cannot see where an organic combination with silver can take place when an emulsion is made *with an excess of soluble bromide*. For that to be possible the silver must have a greater affinity for the organic matter than for the bromine, which would be present in excess of equivalent quantities.

I may say that I have been engaged lately in a series of experiments to endeavour to obtain, if possible, some idea of the probable permanence of the various printing processes of the present day, and more especially to see how much the fading under the various tests was due to the discolouration of the paper, and how much due to the destruction or change of the image upon it.

In common with most amateurs I always use permanent sensitised paper now, and I felt rather anxious as to the comparative permanence of those prints to prints on fresh sensitised paper.

The next series of experiments was to find the difference between some of the bromide papers in the market and bromide papers of my own preparation, the constituents of which I knew to be only washed silver bromide and gelatine in different proportions.

The last series was to discover the power that these various prints would have of withstanding the destructive tests to which they were put when compared with platinotype prints, the unfailing permanence of which we have always been taught to consider an article of faith.

I must leave to a future communication the result of these experiments, but I wish to say that I undertook them solely for my own information, and that I have not the faintest possible interest either commercially or by prejudice with any process.

HERBERT S. STARNES.

DEVELOPMENT OF DRY GELATINE PLATES IN HOT CLIMATES.

THE following account of the system I generally follow in developing dry gelatine plates during the hot weather in Calcutta may be of interest to many readers of the ALMANAC living in tropical climates,

though it is only applicable to places where a supply of ice is obtainable.

In the first place, I do all my development, when possible, in the *early morning*, when the air is coolest. I have a supply of ice ready, and put half of it into the washing water in the developing room, reserving the remainder for the final washing. The plates are first wetted in a tray containing iced water, and meantime the stock developer is diluted with iced water and the plate developed. It is then well washed with the iced water, and placed in the alum bath, as usual, then again washed with iced water and fixed. After fixing, they are well washed for an hour or two with constant changes of iced water, pieces of ice being also placed in the washing box, and are then dried off as quickly as possible. Under ordinary circumstances good plates stand this treatment very well, and do not reticulate. When the temperature is much above 90°, only plates made with the harder descriptions of gelatine should be used.

LIEUT.-COLONEL J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

RETOUCHING AS APPLIED TO COPIES AND ENLARGEMENTS.

THE difficulties presented to the retoucher, when working up negatives taken from some very old and faded photographs, are indeed considerable, and in most cases demand very considerable skill to succeed in producing a satisfactory result. Negatives taken the same size as the original will be found quite bad enough, but still more so are those enlarged from, say, the ordinary photographic *carte-de-visite*. They will have a very coarse quality and present a bad and granular effect almost invariably, which defects are naturally due to the texture of the paper in the original.

In retouching such a negative the first thing to be done is to decide what effect we are desirous to produce. If only to make the copy passable a slight amount of work may suffice; but, on the other hand, if we desire to make the best possible result, we will have a long and very wearying work before us. In such a case general effect rather than extreme fineness of touching should be our aim. I say this because a retoucher with taste can produce a soft effect which will yield a good printing texture with comparatively a small amount of work, whereas should he try to thoroughly get rid of the grain of the paper a very long and complicated work lies before him. Besides, the result will, even then, be anything but commensurate with the amount of skilful labour expended upon it. To aid in getting this soft effect the retoucher should keep his eye as far as convenient from the negative while working it, as he will thus lose the offensive character of the grain more readily.

If it be possible to have the original as a guide while working by all means have it. It will be a great help when putting in the lights, and aid us in avoiding the danger of exaggerating them. Of course any exaggeration in this regard would tend to give the appearance of hardness, whereas all our efforts should be given to the production of softness. Having made up our minds as to the treatment of the texture of the paper, we, of course, would then proceed to the general retouching of the face, which would be carried out in a similar manner to that of one taken direct from life.

The reproductions made from the old Daguerreotypes will be very much less exacting and troublesome, for the mere reason that the negatives in these cases will be quite free from all texture, owing to the quality of the polished silver plates. All Daguerreotypes show a bright surface to the light, and will, therefore, lend themselves to the process of reproduction much more satisfactorily than would an old and faded silver print. Indeed, it will be found that nothing beyond the ordinary modelling and general softening will be required. I have seen many negatives taken from such pictures give a much better result than the original. As I say, the face will be all right, but often the figure will not stand out from the background. This defect will not be so visible in the reproduced negative, as there will be much more contrast than in the Daguerreotype.

There are many difficulties in the way of copies of oil paintings. I have had one very notable case some years ago. It was a life-size portrait of a lady wanted copying. Quite a dozen negatives, varying from quarter to whole-plate sizes, were taken, but all seemed most horrible. For some time no one could see the reason for the markings in the negatives. The painting was a very smooth work, most finely and carefully done, highly glazed, and showing a good surface for photographic purposes. Indeed, really good negatives were taken, but the face was very badly seamed with dark markings running across it from right to left. At last it was found that the

varnish had turned yellow in parts and hence all our trouble. This we thought could be easily altered by asking permission to remove the varnish and have it done afresh, but this proposal did not meet with the approval of the owners of the picture, who said if it could not be photographed without touching the original they would not have it done at all. There was nothing, therefore, but to have the negatives most carefully worked up. This was done, and the pictures turned out successfully. In such cases care must be taken to preserve the likeness and not interfere with the drawing. This is no easy matter where so much has to be taken away.

The difficulties in the way of copying oil portraits, or indeed any other class of pictures, are not so numerous or troublesome as they were some years ago. Mr. Dixon has shown us some wonderful results with his orthochromatic plates, and negatives taken by his process will not require anything like the amount of work demanded by a negative taken in the ordinary way. These plates do not altogether do away with the retoucher's work, but they more than cut his labour in two.

In many cases it will fall to the retoucher's lot to alter the background of a portrait—if it be too dark, to lighten it, and if on the contrary it be light and should be required darkened, we must be prepared to do it. In a case where it is too dark and we desire to lighten it, the simplest way is to coat the back of the negative with either a white or yellow varnish, give it a few moments to evaporate, and before it becomes quite dry run a line all round the figure with a penknife, and then remove the varnish from the figure, only leaving it on the background. This will cause the background to print much lighter. In taking away the varnish it will always be better to leave a little line behind the figure than to take away too much. Should it be only one side that requires lightening, use the ordinary matt varnish, and then take a stump charged with plumbago and work on the part or parts requiring to be lightened. This done be sure to soften the edges well by rubbing with the finger or a clean stump, as failing to do this we may leave a defined marking which would completely mar our picture.

If, on the contrary, we have got a very light background, and a dark one may be desired, or some offensive piece of furniture may require removing, we must proceed in a very different way. In such a case put the negative in the retouching desk, then with a very sharp and pointed knife cut away carefully round the figure. In this way, if desired, we may completely cut away the entire background, or leave us such portions as will enable us, with the brush and pencil, to put in any fresh background and accessories that may seem most appropriate. Great care must be taken should the face be profile, as the least false touch would ruin the picture. In such an operation the arm should be firmly fixed, so as to avoid the chances of slipping and perhaps taking a piece out of the face of the picture. The knife, too, should be extremely sharp, and if used by a steady hand the gelatine film can be cut down and still never come to bare glass. Many retouchers use a needle fastened in a piece of wood to scrape away the background surrounding the figure and face; but, personally, I have always used the knife, and it has always rewarded my confidence in its powers. If the artist be skilful, a negative can be so treated, and a background put in with the pencil and brush that will look quite as though it were the original one. With the gelatine films of to-day it is much easier to avoid a hard outline round the figure than in the old collodion plates long ago. Indeed, the former lend themselves completely to the use of the knife. It is a matter of no moment to cut down the offensive lights that might show on the negative of a lady dressed in black velvet or plush. I refer to the unfortunate wrinkles and light that often show about the bust of a lady, and which may be the result of bad posing or carelessness.

There is another manner of stopping out a background, and that is by masking it. But this has many disadvantages, not only in the difficulty of doing it properly upon the negative, but also in producing prints fairly alike afterwards. However, by a judicious use of these hints, a great deal may be done to make a picture, if not absolutely so, at least passable, that otherwise would be simply impossible.

In all reproductions or enlargements the prevailing fault is flatness and what may be termed want of light and shade. Even in life-size portraits the judicious use of the stump may produce a light upon a face that will make a success of the picture. These lights are not so very necessary where the copies are printed in carbon as they are in plain silver printing. In the former they can be all rubbed out in the *print* and brilliancy thus secured, but the silver print would be quite flat, and nothing would possibly alter it.

Having said so much about the manner of obtaining *lights* in a copy or enlargement, I must say a few words about what is of quite equal importance, that is, the deepening of shadow. Many times in copies and enlargements the shadows are very weak and devoid of all quality

from a printing point. This, however, can be materially altered. The lines and markings, too, in people advanced in years, the texture of the face, &c., are far too harshly marked in the enlarged negative. All these, however, can be much softened, and almost taken away, by printing through tracing paper over the negative, and so interposing a certain thickness of tracing paper between the negative and the sensitised paper.

When doing a negative like this, say a 24×18 size, I always strain tracing paper on the reverse side of the negative. It will serve a double purpose, inasmuch as it not only softens the printing, but is a first-rate medium for working upon with either stump or pencil to strengthen the high lights. I can also by its means deepen the shadows of drapery, or other objects that may require treatment.

To do this I make up a bottle of varnish made of one drachm of Canada balsam and one ounce of benzole. I dip my brush in this and pick out the shadows I wish to strengthen upon the tracing paper. The Canada balsam making the paper considerably more transparent in the places touched by it, the light acts more quickly, and necessarily ends in greater depth of shadow being procured upon the print. The distance the paper is from the film thoroughly softens the edges that might otherwise exist. In this way, with care and skill, a good picture may be obtained of a copy or enlargement from a most unfavourable negative.

REDMOND BARRETT.

MISCELLANEOUS SUBJECTS.

PROFESSOR HOUGH'S EXPERIMENTS ON DEVELOPING-ROOM ILLUMINATION.

THE recently published experiments by Professor Hough, of Chicago, on the relative visual and photographic intensities of red and yellow lights, are in the right direction, what is required being the reduction of the various elements of the problem to figures, leaving nothing to the imagination; I wish, however, that he had used the pure colours of the spectrum, and not the colours of commercial products liable to vary with every specimen. He employed the cloths known as "golden medium" and "cherry medium," with a sperm candle behind each, then tested the fogging power of the light, but he does not carefully describe the conditions of his experiments. Assuming him to have used but one or two thicknesses of these cloths, he was in reality employing a proportion of white light for development. Let a piece of the yellow bookbinders' cloth known as "golden medium" be held between the eye and the sun, it will be seen to be full of small holes freely transmitting white light; put it under the microscope and transmit sunlight through it, dozens of holes will become visible for every single hole seen by the naked eye, and the patchy nature of the colour will become manifest. Three thicknesses of the cloth are necessary to get anything like a surface even in translucency and colour, but then a stronger light than a sperm candle is desirable; so in the absence of information to the contrary, my assumption is that Professor Hough was not testing yellow light, but a mixture of white and yellow. As a practically efficient screen, I recommend three or four thicknesses of dry tissue-paper of a bright sunflower yellow colour, placed between two sheets of common glass, and made to form a lantern window not less than a foot square; behind this, at a distance of nine or twelve inches, have a stearine candle flame; the best hard stearine is cheap and does not gutter. Professor Hough acts upon Fraunhofer's measurements of the luminous intensity of various parts of the spectrum, but his measurements are antiquated; there are others of later date and more exactitude, made also with the diffraction spectrum, in which spectrum the colours are spread out in proportion to their wave lengths, and are not squeezed together at the red end.

What is ordinarily termed a "safe light," is not necessarily the best for developing; there is more comfort in developing with an unsafe light + brains, that is to say, with a practical knowledge of how enormously the fogging power of a light diminishes with increase of distance and under varied conditions. It is easy to develop with a candle down in one corner of a moderately large room, and to apply the developer at the farther corner, with your back turned to the candle, but directly that candle is covered by the flimsiest of yellow screens, the safety of such "development by distance" is considerably increased. By a still farther application of the principle, I like a yellow lamp of large luminous uniform-surface, the light from which is practically unsafe in developing operations at six inches distance; there is then plenty of light in the room, safe to work by, but not near the lamp at particular times and angles of development. The more sensitive the plate the farther from the light should it be when it is taken from its slide and put into the dish, but to do this a good light is not necessary. After it is in the dish, and the developer is over it, it has become at once less sensitive to fogging influences from

at least three causes: firstly, because of the immediate action of the developer upon the surface of the film; secondly, because the plate cannot be tilted to a great angle to the light and receives vastly less of the luminous intensity per square inch; and, thirdly, because some of the incident light is reflected from the surface of the developer, and never reaches the plate at all. Under such conditions the plate may perhaps at once be brought within the six-inch unsafe distance without fogging; this but furnishes an instance of the frequently misleading nature of the testing of the safety of lights by means of plates in a dry state held at right angles to the luminous radiations.

Another point of incompleteness in the experiments by Professor Hough is that he employed but one brand of plates in his experiments, and those were of the "lightning" description. Very rapid plates have been publicly stated to be more sensitive to yellow rays than those which are slower, and except for special purposes I think that few experienced photographers care much for lightning plates. A variety of plates should have been used in the experiments.

In London a proper yellow light is now extensively used for development, and going back to red light is talked about as one misfortune likely to result from the increased employment of orthochromatic plates. I suspect that the most comfortable way of developing the latter may possibly be by brains rather than by what is usually called a "safe light." By the study of the effects of light at certain angles and distances I expect that yellow light may hold its ground, or that a compromise may be effected by utilising the orange rays. Those orthochromatic plates which are not much sensitive to the red rays, consequently are not particularly orthochromatic, will most favour the use of red light in development.

Some persons in London were having their eyesight injured by working in ruby light, and the trouble was removed when they took to yellow. I can quite understand a bad yellow light being worse than a good red one when tested, and surmise that Professor Hough took yellow screens full of minute holes transmitting white light, and compared such yellow screens with red glass.

OPTICAL NOVELTIES.

A few days ago Lord Rayleigh exhibited a curious experiment at the Royal Institution. He said that our sensation of colour is threefold except in the case of colour-blind persons, whose vision is twofold; to normal eyesight all colours whatever can be produced by suitable mixtures of the red, green, and violet of the spectrum. He then proceeded to make yellow by mixing green and red. He projected a spectrum upon the screen by means of the electric lamp, then interposed in the path of the rays a glass trough which cut off all the rays more refrangible than the green, leaving only the red, green, and yellow. He next took another trough filled with alkaline solution of litmus, which, when used by itself, was seen to completely obliterate the orange and yellow rays. When the two troughs were used together, only pure red and green rays passed through them. He mixed these rays, and a full yellow, inclining to orange, was the result. Doubts have often been expressed whether mixed red and green rays will make yellow, and Lord Rayleigh told those present that when they reached home, and were told that red and green will not make yellow, not to believe the statement.

Quite recently, also, some novel experiments were brought under the notice of the Physical Society by Mr. C. V. Boys. He made some glass filaments finer than those of spun glass, by heating the glass more, and drawing it out at higher velocity than by the glass-spinner's wheel. Straw arrows, some five inches long, shot from a cross-bow, were made to draw out the glass, which was first heated by a small oxyhydrogen flame. A filament forty or fifty feet long was made at each shot. By this method he drew also threads of garnet, quartz, ruby, and other materials. The fine quartz filaments had the full strength of steel, their breaking strain being about fifty tons to the square inch, and some of them were so fine that they could not be seen under the microscope except as diffraction bands. He built up a diffraction grating by fixing short lengths of glass filaments side by side upon a piece of glass at the rate of two hundred and fifty to one-tenth of an inch.

W. H. HARRISON.

WHERE I WENT WITH THE CAMERA.

TO HARWICH, THENCE TO ROTTERDAM.

No. I.

WYNTHE-MELVILLE, in his *Holmby House*, says, "Photography, forsooth, is no invention of this nor any other century. It came with mankind fresh and perfect upon earth. When Adam left the garden and knew he should see it no more, he took with him into the dreary waste of the outer world an impression of his paradise that had not faded when his

eyes were dim and his years had numbered nine hundred one score and ten. Eve, too, carried another in her aching bosom, though she could scarcely see it through her tears. Their children one and all possess the art and its appliances." I fear it is going a little too far back to credit Adam with a permanent picture of the Garden of Eden. It reminds one of that story which turns up every now and then of the murderer whose villainous features were found faithfully portrayed in the eye of his dead victim, and by this mysterious evidence was tracked, taken, condemned, and executed.

As I sat reading these first impressions and photographic operations by Whyte-Melville's method, I pictured to myself how Adam would have looked clad in his verdant garb moving about, posing, and taking groups of all the animals wherewith the garden was so plentifully supplied; then looking down at my traps as the train sped on I thought, "It's a long time ago; things are different now; we don't take pictures on sensitive hearts. We use gelatine plates, and our method is much more troublesome." And yet there is something to be said for Whyte-Melville's process, for no matter how many negatives we make upon a journey, pictures upon pictures that we cannot so take will be impressed upon the tablets of our memory, that we may perhaps give word sketches of, but never print from plate. A psychological photography, for which no patent can be had.

On my way to Harwich for Rotterdam, to make the journey easier I dropped in upon a friend and stayed for a day at his place. I took several groups. I took himself, his wife, and his house, and packing them carefully, brought them away with me. When there I heard a good story about this house my friend inhabited which is worth telling.

After the labours of the day were over, as my friend and I were sitting in the dining-room enjoying a smoke, my attention was attracted to a really fine enlargement hanging over the chimney-piece. "A good picture that," I remarked, pointing to it.

When my friend with a smile replied, "Yes, and it has been a good picture to me more ways than one."

"How?" I inquired.

"Well, strange to say," he began, "it's in connection with this very house, and that long before I had any idea of being its proprietor. There was an artist residing here at the time I speak of, and he was the sort of man that got into debt with everybody, and would pay nobody."

"What do you mean? Was he hard up, or what?"

"I do not know why he should have been hard up. He had lots of work to do, and it paid well; but no one that he was indebted to could get money out of him. I did not know of this peculiarity in his character, and as luck would have it I unwittingly lent him a good round sum. After waiting some time I tried to get my money, but in vain, so I resolved to give the matter into the hands of a bailiff. I called upon one with this intention. When he knew what I wanted he said, 'It ain't any good, sir. I can't do it. I've been a-trying to get into that man's place for months, and can't no way.'

"How is that?" I asked.

"He's too dead fly, that's what he is," replied the officer with a knowing leer. "Why, the gas company could not get their account no way, and they thought to get the best of him anyhow. So they wrote him that on a certain day they would break open his door and take away their meter, and by this means would get into the house, and take possession for their account."

"And how did he get over that?" I asked.

"Oh, easy enough," he replied. "When we went to take away the meter it was waiting for us on the front doorsteps."

"We must get over him somehow," I said, with determination. "I'm not going to lose my money."

"Look ye here, sir, it's just wasting money. I have now an account o' Slasher & Co.'s for forty pounds odd. I've been a-prowling around that place for months, and it ain't no good. He's too dead fly, I tell ye. You never find him a opening of that door; he puts up the window and speaks to you there, but you don't get no nearer."

"We'll have a try, at any rate," I remarked, as I left the baffled officer. "I'll see you again shortly."

"So I came home, thought the matter over, and after arranging a plan in my own mind, took down that very picture and carefully sewed it up in green baize. After that I had my friend the bailiff to do himself up as much as possible like a dealer in pictures. I then had my picture taken down to the railway station and put into the left luggage office. I knew that my artistic friend had correspondents and friends in Reading, and I had in my possession a visiting card of a personal friend of my own who resided near there. When the train from Reading came into the station I had the officer ready with a friend on the job to take the picture out of the left luggage office, hire a cab, and drive to the artist's house. Arriving there, the cabman was sent up to the house with the card. The window was thrown up, and the wary one called out, 'Well, my man, what do you want?'

"Two gents, sir, here with a picture," said the cabman, touching his hat. The cabman was perfectly innocent, you know, and he handed the card in good faith as he said, 'They want you to come down for it, sir.'

"Where do they come from?" asked the painter, suspiciously.

"Station, sir. Reading train just in."

"Well, go and fetch it up," said the artist, not moving from the window.

"Won't let me, sir. I asked to. Said it was too valuable."

"The cabman's manner evidently gave confidence to the cautious one, for he ventured to open the door, and came down the garden to the eab. He asked a few questions, which seemed to satisfy him."

"This picture," said the officer, 'is of considerable value, and it must be very carefully handled. It has to be cleaned and restored, and we have been recommended to you as a gentleman who will do the work satisfactorily if you would undertake it; but it's no use our lifting it out unless you see your way to do it.'

"This seeming carelessness allayed his suspicions. After a little reflection he said, 'Well, bring it up to the house.'

"Carefully the cabman and the officer carried it up, and entered the door."

"Put it down in the hall," said the artist, as he stood behind them ready to shut the door as they went out.

"Laying down the picture, the bailiff turned to the cabman and said, 'There's your fare; send up that other fellow here.' Then taking off his hat and wig, and turning to the artist with a leer, he said, 'It hasn't been an easy game, governor, but there is no blooming error, I'm on the right side of the door at last.'

"Sold, by heavens!" exclaimed the artist, livid with rage.

"You see you dare not break into the house," continued my friend, "but when once in you can hold possession till you get your money; and you know in this case the bailiff could open the door to all and sundry that might call for accounts. So he was obliged to be got rid of. The two accounts were paid in full within an hour."

"That was smart," I said, as I again looked up at the picture with the history.

Next day I reached Harwich, and at night took boat for Rotterdam. It was very dark. When we started nothing could be seen but here and there a few flickering lights that reflected and moved in the water like wavelets of gems. On churned the steamer through the mirk, and as I stood leaning over the bulwarks smoking the pipe of peace and peering out into that black gulf of seeming nothingness, I thought, "This night—all night—every night all the year round, thousands and thousands of human beings are moving on the bosom of the mighty waters, coming and going, going and coming; weaving the stories of lives, warp or woof are they; protecting the interests of countries, plotting the downfall of empires, building histories; each one with his motive, pleasure or profit, bringing in his trail love and joy or hate and misery, heavy hearts and light. The hopeful and the hopeless all over the world are moving on the ceaseless waters—this night—all night—every night for ever and ever." To weave another thread into the pattern of the story of my life, I went away down to bed.

When I got up in the morning, I found we were steaming up the River Maas. The morning was cold, grey, and misty, and the first look out upon the borders of this new country was novel in the extreme. The low lying table-land flat and uninteresting; the little clusters of houses built in every conceivable style, form, and colour; the knotted, grotesque willows, and scraggy vegetation, all impressed me with the idea that the place had been laid out after the plan of the imported toy-box—a whole-farm-for-one-shilling, sort of thing. By-and-by the sun came out and brightened up the scene, all the picturesque effects flashing out in a moment, lighting up the little houses, the little trees, the little canals, the little bridges, and by that one magical touch of sunshine a charm was lent to the scene, rendering it quaint, curious, and interesting. We now slow to let the Custom House officers come on board, and the luggage is brought together for their inspection. I had some doubts about my photographic plates, so I went on to the upper deck and stood looking over the rail at their progress, till they were nearly done. One of the officers looking up at me then asked if I had no luggage. Oh, yes, I had luggage, and I brought it. I explained about the plates which they handled suspiciously, only for a moment, and then pressed them carefully. The only thing that seemed to bother them much was my tripod stand—it was a new pattern with a good many screws, and I had it fixed in the middle of my bundle of rugs, the two ends protruded exposing all these screws. They stood wondering what sort of a machine it could be, and evidently making up their minds that it was something infernal, until I explained their doubts away, and then they were happy, and so was I. I cannot pass here without tendering a word of thanks and praise to the Customs officials all over the journey, for, on an explanation, they did everything in their power to protect both plates and negatives, and I never had a moment's trouble or uneasiness.

Oh, the delicious leisure with which these Hollanders do anything and everything. After the hurry and worry of life at home it is perfectly charming. The boat gets alongside the quay; by-and-by they begin to think that we would be the better of a gangway put across so that we might be able to get ashore, and so they set about it. From a windlass they unwound a chain with a hook on the end, which is put into an iron loop fixed in the gangway; in trying to lift the gangway, out comes the hook, and away swings the chain right across the deck within an ace of breaking three or four heads, and actually knocking down three or four boxes. With a broad smile, a long "Yah!" and a slow, decided footfall, the Dutchman goes on his way rejoicing, catching up the swinging chain, readjusting the hook, and after ten minutes of slowly

winding, the gangway is safely placed across a gap of three feet. Then, with some promptitude, I thought that I would let them see how we did it, and tried to hurry up the slow ones with my luggage. Getting into the 'bus, I ordered the driver to make all haste for the city; but really it wasn't much good, the driver mistook noise for speed, and he kept yelling to the horses all the way, but they knew better, and would not be hurried, but trotted on in their easy-going way, taking no notice of the driver whatever.

MARK OUTE.

THE HISTORY OF PHOTOGRAPHY.

On Friday evening a lecture upon the history of photography was delivered in the Lecture Hall, Tower-street, Ipswich, by Mr. William Vick, in aid of the funds of the children's wing of the East Suffolk Hospital.

Mr. Vick spoke of the invaluable service photography rendered to all sorts of people; nothing came amiss to it, from the most gorgeous eastern temple to the last new thing in bonnets, and nothing in all the records of science had in forty years obtained such world-wide appreciation. The germ of photography—the dark room—was discovered by Porta in the second half of the sixteenth century. His camera obscura was a room into which the only light admitted came through a small hole in the shutter. The effect of light upon certain chemicals was accidentally discovered by an alchemist, who one day threw some sea salt into some nitrate of silver and thus formed chloride of silver, which had the quality of turning black when exposed to the light. Mr. Vick showed how chloride of silver was formed by pouring some salt into some nitrate of silver. If that was taken into daylight it would become black. Professor Charles made the first use of this with the dark room. In giving lessons to his class he exhibited some startling experiments. By means of a strong solar ray he threw the profile of a member of his class upon a piece of white paper covered with chloride of silver, which took the impression in white upon a black ground, to the amazement of those present. But the impression was not permanent, and the effort to obtain something which could fix it occupied the minds of many scientists, amongst them James Watt, of steam engine notoriety. In 1826 M. Daguerre, the inventor of the diorama, and M. Niepce, each of whom had made experiments in that direction, entered into partnership and worked in common to fix the image afforded by the camera. Niepce discovered the use of mercury and iodine of silver, but died before the work was finished, and Daguerre was left to carry it on. Daguerre worked on, and eventually, with Isidore Niepce, the son of his former partner, formed a company and brought out the Daguerreotype process. This they transferred to the Government, Daguerre receiving a pension of £6000 and Isidore Niepce one of £1000 in return. Mr. Vick showed the working of the Daguerreotype apparatus, which he had with him. To have his portrait taken by the process a man had to sit for a quarter of an hour or twenty minutes. He did not know what people would say if asked to sit so long now. It often happened that inventors, having once invented a thing, could develop it no further and died poor, while others who came after and improved the invention reaped the fruits of their labour and died rich. Daguerre gave the world the first rudiments of photography, but his genius could take him no further, and he had to leave it to others to develop the art. Collodion, as a coating to receive the impression, which was discovered by Mr. Scott Archer, revolutionised photography and was in use for about thirty years, but now it had been displaced by gelatine. Many other things were sensitive to the effects of light in this way, and even a deal board was capable of receiving an impression. Whatever might be said against photographers it would not be denied that they took a deep interest in their work. One of their most frequent sources of complaint was that sitters would not allow them to do their best to turn out an artistic portrait but would impose absurd restrictions, which they would never think of doing if they were going to have their portrait painted by a celebrated R.A. Several amusing instances of this were shown in views upon the screen; of the lady with the snub nose who wished to be taken in profile because the portrait of some pretty young lady friend taken in that way was "so satisfactory;" of another lady, with eyes all akimbo, who insisted upon being taken full face "as if she was looking at you;" of the gentleman with a pair of legs rather bent and not at all elegant, who would be taken standing; and one with a particularly long pair, who would be taken sitting. Very much had to be done by tact and equanimity of temper. Only the other day a man complained to him that one side of his face was taken darker than the other, whereas "he was not born so." To argue with a man like that upon the question of light and shade would be like easting pearls before swine. Several anecdotes of the comic side of the art were also narrated, and a copy of Du Maurier's picture in *Punch* of the photographing of the firstborn was shown upon the screen. If they wanted to try the patience of a photographer let them bring the mother, grandmother, aunt, father, grandfather, uncle, and a few others, and set them all to amuse the baby whose portrait was to be taken. During the siege of Paris, 1870-71, the pigeon post was very largely used. The messages were reduced by photography and fixed inside a quill, which was fastened to a feather of the tail of the pigeon. When the bird reached its destination, the message was taken into a darkened room, and with the aid of the oxy-

hydrogen microscope thrown in magnified size upon a white sheet upon the wall, while the reporters sat at a table and copied it. It was possible for one pigeon to carry about 3,000,000 letters of the alphabet in that way, and more than 100,000 despatches were sent into Paris during the siege. Photographs could be taken upon wood, and also upon silk and textile fabrics, so that if they wished to mark a handkerchief so that they should know it again, they could have their photograph put in the corner. In conclusion, Mr. Vick gave a practical demonstration of the rapidity with which a permanent photograph could be developed. He developed a negative in the usual way, and passed it to the gentleman in charge of the lantern, and the portrait of Jim Frost, the well-known Ipswich crag vendor, was thrown upon the screen, the whole process having lasted only a very few minutes. He also took a number of prints upon pieces of textile fabric. He was warmly applauded at the conclusion of his lecture.

SNOWSCAPES.

LIKE the man who could not see the town for the houses, the photographer who waits for leafy June before he begins to take landscape views will not be able to see the country for the foliage. When heavy shade trees overshadow all picturesqueness, we sigh in vain for light, since we know, alas! how imperfectly our sunbeam pencils sketch in the dark. Hence these days of early spring tempt us to leave lantern slide making and transparency work, that we may discover what a wonderful light reflecting medium is the white snow. Maybe it has already begun to melt in patches, yet surely there is enough left for our 4×5 and 8×10 pictures. We imagined winter had laid nature bare, but instead we find he has covered her with ermine fit for earls, and hung every twig with pearls and diamonds. This is a magic world; one hour the fields are as solidly white as the whitest coated dry plate, the next as wet as the wettest plate of old process days. Here a view of melting snow gives us a Niagara in miniature, and again ten feet of ice glisten in our camera like a a mile-wide river in a skating carnival.

If only for scientific experiment, it is interesting to note what swiftness of plate and shutter snowscapes require, the maximum of light being as great as at mid-ocean. Again, artistic amateurs will be delighted to find twenty objects, such as cowshed and wood pile, made beautiful as picture material when covered with snow; and since fashion has made certain old-time sports famous, any one who wishes to turn an honest penny into needed acid or plates can do nothing better than to photograph a toboggan party. Or to choose simpler material, let him shoot at our street gamins as they race down hill on their long "hobs." Better yet, since work makes hay of life, will be the realistic view he can take of the same lads dragging their heavy sled up the steep slide for a second dash. Sometimes gallantry will have led them to give some little sister a ride up hill; more often some work-shirking boy—destined to get free passes on the railroads by-and-by—will be seen lying face downward on the high board seat, and in either case the additional figure will give an interesting feature to the picture.

Children grouped about a rudely made snow fort make good subjects for the home artist, who simply wishes a suggestive portrait of Charlie or Tom; a single figure rolling up a big snowball; a plough making its slow way through shining drifts; an unbroken wintry road; a crusted lane; *verglas* on maple boughs against a background of dark evergreen trees; all give delightful bits as new to photography as midsummer landscapes are old.

To outing lovers, iceboat racing, groups of skaters and trotters are pleasing, but less observed scenes, such as the breaking up of our frozen river in early April, make more original pictures. A 4×5 view of one huge ice-boulder crashing up against another; a black pool between them; a curve of snow-crusted pebbly beach beneath, blue sky above, has all the feeling of the Rhone glacier about it; yet only fishermen spreading their shad nets note these common everyday sights.

Snowscapes are specially attractive when finished on rough bromide paper, where soft blackness and whiteness lends itself to the chance-like sketch. It is against the printed rules, yet a certain Christmas-card sparkle and glitter, inartistic but realistic, is obtained by adding a few additional drops of iron to the developing solution.

For all this outdoor work avoid taking cold, as well as views, by choosing a day when the mercury is above 40°; there are plenty ahead of us before the grass grows green. Wrap up warmly; the focussing cloth may be worn as a black cloud around the ears, and as far as possible make all preparations before leaving home. Also remember the advice given to tourists last summer. Before setting out with tripod or detective bag choose your view, make your appointment with the sun and keep it. It may be said, for the less hardy among us, that many beautiful scenes can be taken from one's own window—views which are sometimes pronounced "too dreadfully dreary and lonesome" by those who, having eyes, yet see not, but which are very charming to the artistic amateur.

Avoiding, then, those zero days when the most highly advertised slides will not pull for frozen fingers, let us choose a mild thawing noonday before the April sun has wasted the snow quite away, and secure pictures of ice-palaces, glaciers, and toboggan slides, the very sight of which shall cool us when we frill and blister next August.

ADELAIDE SKEEL.

—Anthony's Bulletin.

FAREWELL DINNER TO MR. W. K. BURTON.

On Wednesday night, March 30, a farewell dinner was given at the Holborn Restaurant, London, to Mr. W. K. Burton, C.E., as a token of the esteem in which he is held by his friends, and as a farewell meeting before his departure to Japan, where he will occupy the post of Professor of Sanitary Engineering in the Imperial Institute at Tokio. Mr. W. H. Walker, of the Eastman Film Company, presided. The company numbered about fifty.

After the usual loyal toasts, the Chairman said, as an American, he once had never expected to meet Mr. Burton, who was well known to him by his writings, but of late he had numbered him among his few personal friends; he was both surprised and pleased at the great honour of having to occupy the chair that evening. No writer upon photographic subjects had greater influence over photographic readers than Mr. Burton. He then proposed the toast of the "Army, Navy, and Reserve Forces."

Mr. A. B. Brown, of Edinburgh, responded for the Navy, and Mr. A. Pringle for the Army, which he said he had entered as a drummer and retired from as a trumpeter. The army with which he was now connected was the noble army of photographers.

Mr. J. Traill Taylor read letters from Mr. W. S. Bird, Mr. O'Farrell, Mr. Howard Farmer, Mr. S. McLellan, Mr. Cocking, and others, who from illness or other causes were unable to be present.

The Chairman then, in the name of a few friends, presented to Mr. Burton a chronograph and gold chain, as a small memento of the esteem in which he was held, and to show how they appreciated his abilities and his kindly and genial nature; he hoped that every tick he heard from that chronograph would symbolise to him a pulsation from the heart of every one present that night.

Mr. Burton responded that the Chairman had spoken of him beyond his deserts; what had been done that evening had more than pleased him, for it had affected him to see so many present who had come out of good feeling, and all of whom he recognised as good and true friends of his own; he saw present fellow-schoolboys, fellow-apprentices, fellow-workmen, and his former master, Mr. A. B. Brown, whose presence that evening he considered a great honour. In addition he saw present a great number whose friendship he had made through photography, the subject which was nearest to his heart, for he had loved it more than any other pursuit. He heartily thanked every one present, also those who had been unable to attend. In a few days he had to begin a journey of about 12,000 miles to a far country; he should remember those he had left behind, and bear with him the magnificent present which had come upon him quite as a surprise when he accidentally heard of it for the first time that morning. He knew that those who were absent had good reasons for not attending, and he should remember all his friends until he was able to return to this country once more.

Dr. Thomson said that he was the oldest friend of Mr. Burton present that evening; he knew him when he was in petticoats, twenty-five years ago. He was the son of a very distinguished father, who occupied a high position in the literary world, and held an important official position in Scotland.

Mr. Taylor said that Mr. Burton had descended from good old photographic stock; he was the grandson of the late Professor Cosmo Innes of Edinburgh, who had been an indefatigable worker of the paper processes a quarter of a century ago.

The Chairman proposed "The London and Provincial Photographic Association," to which Messrs. Ashman and Prestwich responded.

To the toast of "Professional Photographers" Mr. A. L. Henderson responded.

The Chairman proposed "Landscape Photographers," coupled with the name of Mr. Bedford, who, in responding, said that his friend Burton would be very much missed indeed in the photographic societies; in London he had held a thoroughly independent position in photography. Mr. Taylor proposed "The Photographic Convention of the United Kingdom."

Mr. J. J. Bringinshaw returned thanks, saying that the Derby bantling had grown into a very healthy condition, and he hoped to see a large party at Glasgow next autumn.

The Chairman proposed "The London Photographic Club," coupled with the name of Mr. Foxlee, who briefly responded.

The toast of "The North London Photographic Society" was coupled with the name of Mr. A. Mackie, who remarked that it was the youngest of the photographic societies, but it did not interfere with the work of any of the others, as it treated photography from an elementary point of view, and proposed to give elementary lectures to amateurs and beginners.

In response to the toast of "The Camera Club," Mr. H. J. Gifford said the Club had sprung up, he might say, almost wholly from the influence of Mr. Burton.

Mr. Taylor then proposed "The Photographic Society of Great Britain," coupled with the names of Mr. W. England and Mr. W. E. Debenham.

Mr. William England, Vice-President, hoped that Mr. Burton would have a prosperous journey; they all would be glad to see him on his return.

Mr. W. E. Debenham said that it was the oldest Society and had done good work in its time; he believed that all societies had their waves of greater and less usefulness, and he hoped that the Society would have

great usefulness in the future. There was a melancholy tinge in that meeting, as they were about to lose their friend Burton, and his coming back was a long time off. His distinctive character as a writer in the photographic journals was that he did not make experiments and keep them to himself, but he gave away good experiments combined with literary skill. He hoped he would continue to experiment when in Japan.

Mr. A. B. Brown proposed the health of the two photographic journalists, Messrs. Taylor and Bolas, both of whom briefly acknowledged the toast.

Mr. C. Heinrich Trinks proposed a vote of thanks to the Chairman, who was a foreigner as well as himself. His experience was that Mr. Burton's work was well known on the Continent, and that he was appreciated there as a thorough and earnest worker.

The Chairman returned thanks.

Mr. B. J. Edwards asked the company to wish Mr. Burton a safe and pleasant voyage out and home, after which the company separated at a late hour.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, March 31, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. A. Pringle presided.

Mr. S. G. B. WOLLASTON said that he had seen in print a misrepresentation of a remark of his as to the solvent action of glycerine on gelatine; he had never said that it would dissolve chrome-almed gelatine or that it had a solvent action at all; he had merely stated that when certain gelatine films were obstinate in coming off their supports the addition of a little glycerine would make their separation a comparatively easy matter. Film photography had of necessity advantages of its own; it had been to him, as a peripatetic man, an incalculable boon to be able to take a few spools and no developer with him when travelling, and to obtain with certainty twenty perfect negatives out of every twenty-four exposures. In the packet before them he had sixty paper negatives, all oiled, yet the packet weighed less than ten and a quarter ounces, and its bulk was small. Financially films would hold their own against glass, and if desirable they could afterwards be transferred to glass, as he sometimes did, for it would not do to put flexible negatives into the hands of young assistants, damage being the certain result. Owing to the enterprise of the Eastman Company, M. Thibaut, Mr. Pumphrey, and others, film photography had become possible, but to him practically the list had been reduced to the first two. The density of images upon Thibaut's films could not be judged by transmitted light; truly the films might be intensified, but intensified negatives were never perfect; therefore he found himself reduced to the Eastman stripping film. Those who took up film photography would have to unlearn much that they had learned previously in developing images upon glass; with films he thought that it was almost imperative to give up ammonia development; ferrous oxalate worked with them extremely well, but the use of one of the fixed alkalis was better still, the development then being more under control. Towards the close of development he would sometimes add a little ammonia to give crispness, if necessary. Eastman's films might be used as ordinary negatives by those who did not care to take up the process in its entirety. He exhibited an 8x5 negative upon an Eastman film, then treated a glass plate with French chalk, followed by a coating of tough, plain collodion thinned down, and to which a minute proportion of castor oil had been added; to this prepared plate he intended subsequently to transfer the film. The speed of the films was twenty-two, and in a few cases twenty-five, by the

Warnerke sensitometer. Ordinarily he developed three, six, or nine at once in large dishes. His developer consisted of—

Solution A.	
Pure sodic sulphite	6 ounces.
Distilled water	40 "
Pyrogallol	1 ounce.
Citric acid	1 "

Solution B.	
Pure sodic carbonate.....	4 ounces.
Ordinary water	40 "

Solution for Use.
One ounce Solution A, two ounces } Maximum, five drops ten per
water, and one ounce Solution B } cent. solution of bromide of
potassium to the ounce.

The developed films had to be squeezed down upon the prepared and washed glass plate already described, and the paper would strip off, especially when that operation was facilitated by the presence of a little glycerine in the water. The speaker developed in a bright yellow light, which he said that he had found not to fog the images. He said that he was careful not to expose the developed negative to white light until it had been washed for some minutes, otherwise it acquired a yellowish colour and printed slowly.

Mr. A. HADDOX remarked that the only difficulty about the process seemed to be the obtaining of the paper. When did the Eastman Company intend to send more over?

Mr. W. E. DEBENHAM said that the distortion of photographs due to the unequal expansion of the paper when wet, and afterwards drying the film upon a rigid surface, made the process before them imperfect for portraiture, though it might do for landscapes.

Mr. W. H. PRESTWICH asked if parchmentised paper could be used.

Mr. W. M. ASHMAN asked if any one had tried solution of gold size for varnishing flexible films.

Mr. A. L. HENDERSON thought that Mr. Ashman had made a very wise suggestion.

Mr. H. A. BRIDGE said that gold size dissolved in turpentine made a perfectly waterproof varnish.

Mr. DEBENHAM did not think that intensified negatives were always of an inferior character.

Mr. WOLLASTON wished to qualify his remark on that subject by substituting the word "seldom" for "always."

A vote of thanks was then given to Mr. Wollaston with acclamation.

Mr. WOLLASTON responded that it was a pleasure to demonstrate before an auditory like that, who could appreciate the points. It was not the same with a company of amateurs and ladies, which caused the speaker to finish with a kind of sinking of the heart. He should go away with a very kindly recollection of his reception by the Association.

Mr. HENDERSON exhibited and described a detective camera brought over by an American amateur, and made, he believed, by the Scovill Company, of New York.

The HON. SECRETARY said that it much resembled one exhibited by Mr. Watson.

The proceedings then closed.

CAMERA CLUB.

THE lantern slide exhibition (the last of the session) at the Camera Club on March 31 was the most varied that has yet been given. There was a crowded attendance.

Mr. C. B. WRIGHT sent three sets of slides—views in Norway, pictures in North Devon, and photographs of ruins on the Riviera after the late earthquake. The English series included some very picturesque effects, particularly *A Misty Winter Morning*.

Mr. F. DUNSTERVILLE sent a further instalment of slides of Indian subjects, mainly showing various classes of natives. These excited very great interest.

Mr. PRITH exhibited a very varied selection, including views of Greek and Egyptian ruined temples and pictures of home scenery.

Mr. W. BROOKS showed and explained the peculiarities of some interesting work done five-and-twenty years previously, and

Mr. FRANK HOWARD made a few remarks on the printing-in of clouds in lantern slides, illustrating his description by the exhibition of some combination transparencies done by Mr. Breeze many years ago and by a selection of his own work.

Mr. George SMITH showed a few very fine Woodbury slides of microscopical subjects and general work, and Mr. GALE exhibited studies of picturesque English landscape with figures.

Dr. G. LINDSAY JOHNSON explained a new microscopical attachment for the lantern.

The subject for Thursday, April 14, is *A Demonstration in Photo-Micrography*, by Mr. T. Charters White.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on Thursday, the 31st ultimo, at the Royal Institution.—The President, Mr. George H. Rutter, in the chair.

The minutes of the preceding meeting were read and confirmed.

The following gentlemen were unanimously elected members of the Association:—Captain L. Ching, R.N.; Messrs. W. J. Davey, G. W. Guy, and H. R. Marsden.

The SECRETARY acknowledged the gift to the library by a member of two copies of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC and three of the *Photographic News Year-Book* to complete the library sets; also the photographic journals from the respective editors.

Proofs of the presentation prints for 1886 were exhibited, being 15 × 12 enlargements, executed in carbon by the Autotype Company, of *A Cheshire Lane*, by Mr. A. W. Beer, and *Doorway at Tabley Hall*, by Mr. J. H. Day.

Mr. GEORGE E. BELL, of the Air Brush Manufacturing Company, Rockford, Illinois, exhibited the action of the air brush, and in the presence of the meeting executed in five minutes a large head resembling fine crayon work. The facility with which he worked and his dexterity were much admired. He afterwards explained the construction of the instrument, which is very ingenious.

The competition for the lantern-slide prize was then proceeded with. There were five competitors, who had sent three slides each, which were projected on the screen by means of the Society's limelight lantern, the judges being Messrs. Atkins, Boothroyd, and Sayce. The result of the competition was that the set bearing the motto "Black Diamond" were adjudged to be first, and those with the motto "Gone" second. It was ascertained on opening the envelopes that Mr. A. W. Cornish was first, thus gaining the silver medal, and Mr. A. W. Beer second. The judges also highly commended a slide by Mr. Riley.

The two hundred American slides sent by the kindness of the Camera Club were then exhibited, and excited a great deal of interest, from the novelty, in many cases, of the scenery depicted and the general excellence of the slides.

Some slides were afterwards exhibited, the work of Messrs. Grillon and Faltin; and after passing hearty votes of thanks to Mr. Bell and the Camera Club, the meeting terminated at a late hour.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

A PUBLIC meeting of the above was held in the lecture theatre of the Literary and Philosophical Society's Institute, Newcastle, on the 11th ultimo,—Mr. James Downey in the chair.

Certain business connected with the exhibition came up for discussion. Mr. THOMAS M. LAWS (who acted for the evening in place of Mr. Pike, the Hon. Secretary, unavoidably absent) proposed, and Mr. LYDELL SAWYER seconded, "That a label not exceeding three inches by one and a half inches, containing the title of picture and name of exhibitor, be allowed on the front of each exhibit, also that the Hon. Secretary write to each exhibitor notifying above." Carried unanimously.

The slides sent in for competition were then shown on the screen and the CHAIRMAN announced Messrs. Gibson and Auty as winners of the first and second medals.

There was a large attendance.

The next meeting will be held in the College of Science on Tuesday, the 12th instant, when Mr. Jackson, of the Eastman Dry Plate and Film Company, will give a demonstration of the Eastman stripping films.

HALIFAX PHOTOGRAPHIC CLUB.

THE monthly meeting of the above Club was held in the Mechanics' Hall on Thursday evening, March 24,—The President, Mr. Councillor Smith, in the chair.

After the formal business of reading the minutes and balloting for new members had been taken, Mr. George Hepworth read a paper and gave a demonstration in connection with the platinotype process. There was a large attendance, and the subject proved to be one of special interest, and a somewhat exhaustive discussion took place upon the question of the permanency or otherwise of pictures produced by this process, and the opinion was given unanimously that if the instructions issued by the Platinotype Company were carried out as they ought to be, there was not the slightest doubt the results would prove to be absolutely permanent, the paper itself being the most perishable element in all probability.

A very fine show of pictures was placed in the room, a collection being sent by the Company and by members of the Club.

Tylar's metal slides, and Hinton's photographic labels, were shown and favourably commented upon.

Correspondence.

"A NEW LANTERN SLIDE CARRIER."

To the Editors.

GENTLEMEN,—Mr. Hepworth's letter in your last impression is apparently another proof (if such were needed) that two persons engaged in similar pursuits, and suffering similar inconveniences, occasionally hit upon similar means for remedying them. The idea was certainly original with me in February, 1884, and Mr. Hepworth having made some carriers on the same plan in 1883 does not in any way affect this fact. In my previous letter I said the idea was not new, and Mr. Hepworth's letter confirms this. The magnanimity conveyed in the last part of that communication (with reference to the "*lapsus memorie*") is very refreshing; only as I could not possibly have forgotten what I never knew, it scarcely applies to—Yours, &c.

F. A. BRIDGE.

April 4, 1887.

PHOSPHORESCENCE.

To the Editors.

GENTLEMEN,—On pages 722, 739, and 753 of your valuable paper (vol. xxxiii), are some communications relative to phosphorescence phenomena observed in the dark room. I have this day, for the first time, noticed the light, and it was so astonishingly brilliant that the subject seems to me well worthy of investigation. My present communication is merely to state the conditions of the experiment.

I was developing two 5 × 8 plates in an 8 × 10 ebonite tray, and on transferring one of them to a large porcelain tray, containing at least a half gallon of water, in which a single 8 × 10 plate from the alum bath

had been soaked, the whole surface of the plate was instantly covered with a lambent light, which disappeared as the plate passed beneath the surface. A Japanese gentleman happened to be with me at the time, and as I transferred the second plate in the same way, he also clearly saw the phosphorescence. As that was my last plate the experiment could not be repeated.

My developer was pyrogallol with potassic carbonate and sodic sulphite, but without bromide. The water in the large tray contained only the small quantity of alum that was carried in the film of the 8×10 plate. The alum solution from which that plate was taken was strongly acid with oxalic acid.

The plates were made at Passavant's Dry Plate Factory, San Francisco, Cal., U.S.A., and I may incidentally remark that there are no better plates to be found.—I am, yours, &c.,
Osaka, Japan, February 12, 1887.

R. HITCHCOCK.

THE OWNERSHIP OF THE NEGATIVE.

To the Editors,

GENTLEMEN,—Perhaps you will kindly allow me one word on the question of the ownership of the negative, raised by the letter of Mr. Debenham, of Ryde. I have been a photographer since 1854, and all these years I have never seen the question fairly put and fairly discussed. Photographers discuss it from their own point of view; they please themselves. But their view of the question is a most selfish one. Printers' types and photographers' negatives are not alike.

The negative, I consider, belongs to neither photographer nor sitter, but in the interests of both it ought to be destroyed. Photographers, be they ever so eminent and ever so successful, have received ample pay for their work; they have had their own charge, and ought to rest satisfied with it. Granted the plate belongs to the operator (which it really does not, for he has charged for it), the image upon it does not. He has only arranged in a pleasing form, and fixed that which belonged to and was placed upon it by the sitter. The value of the image and the value of a plate ought not to be compared. Why should a photographer arrogate to himself to be the custodian of treasures so highly prized by his clients? Are not negatives sometimes sold? and by whom? See advertisements in journals.—I am, yours, &c.,

FAIR PLAY.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM LE FLEUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

GRIMSBY.—We cannot name any brass turner who would make such a mount, although we are aware of some who have got such work done.

M. P.—Your best plan will be to make your wants known through the medium of our advertisement columns. This will no doubt secure what you require.

LINDSAY JOHNSON.—The description of the glass mentioned has not appeared in this JOURNAL, but we believe it was published in the *English Mechanic* about two months ago, more or less.

HOME RULER.—Either of the doublet lenses mentioned may be employed as a single landscape lens by removing the front combination. The focus will be about double that of the lenses when used intact.

H. WALKDEN.—Apparently you require detailed instructions in mounting on glass; therefore we refer you to Mr. Armstrong's article entitled *Optical Contact*, on page 118 of our ALMANAC of last year.

S. S. S.—For taking houses close to the camera employ a wide-angle lens with a small stop. The same lens employed with the largest diaphragm may be used with a drop shutter in a bright day and on well-lighted subjects.

GREENHORN.—If the front lens be placed in the back cell with its flat side towards the front, and a diaphragm with a quarter of an inch aperture be placed at not less than two inches in front, the definition is certain to be good.

A. G. C.—Although unable to say what brand of paper the print is upon, yet will it be quite easy to obtain a stout sample from any of the large houses. Almost any kind of toning bath will yield a similar colour, more especially if ammonia fuming be adopted.

ABBOTT writes: "Will you kindly answer, through your 'Answers to Correspondents' column how I can test soda carbonate crystals for purity?"—The only plan is by volumetric analysis. If Abbott is not proficient in chemistry he had better procure the salt from some reliable source; he can then rely upon its purity.

OFFICE asks if there is any means of finding out whether a photograph has been registered or not within a few years. "One I wish to inquire about is a portrait of a gentleman (name is known, also the photographer's name)."—Yes, it can be ascertained by searching the records at Stationers' Hall. This must be done personally.

A. J. JONES, of Moss side, writes, denouncing the accuracy of the report of the Manchester Society's Lantern Section so far as regards the utterances attributed to himself. Instead of saying that he "did not use the dissolving tap because the high pressure was too great a strain on the dissolving tap," he avers that he stated just the contrary.

A. BROWN says: "As my studio is lighted from the east and the sun is getting troublesome, I should like to try the method of softening the light recommended by Mr. T. Protheroe on page 139 of this year's ALMANAC, but have been unable to procure the kind of paper; I shall be much obliged if you can tell me where I can get it."—The paper recommended can be obtained from most wholesale stationers who make fancy papers a speciality. Perhaps Mr. Protheroe will kindly favour our correspondent with the address of the house from whom he obtains that he employs.

S. HOLMES.—The developer you employ is strong in an almost ridiculous degree. Instead of using a saturated solution of protosulphate of iron, try a developer composed as follows:—Protosulphate of iron, a quarter of an ounce; acetic acid, one ounce; alcohol, half an ounce; water, eight ounces. After all the details are out, with as much vigour as can be obtained, an increased degree of density may be given by washing off the developer and applying:—Pyrogallol acid, four grains; citric acid, three grains; water, two ounces; to which are added, at time of using, two or three drops per ounce of a fifteen-grain solution of nitrate of silver.

GRIMSBY, referring to Mr. Harrison's article on the *Education of Photographers' Children*, and on *Guines, near Calais*, as a favourite place for English parents to send their children, says: "As a photographic assistant of twelve years' standing—who has received a foreign education, part of which was received at Guines—I wish to warn parents against sending their children there, as of the several schools in that town, not one is of any good. The instruction imparted at these establishments is a mere 'farce,' utterly worthless, as I soon found out, and had myself removed to a Government 'Lycée'—where, if one stops a number of years, a sound education is imparted."

LOTO writes: "I should be glad to know if anything can be done to save a negative with which I have had an accident. I dried it by means of alcohol, and, feeling convinced it was thoroughly dry, I put it in the printing frame, and on going to look how it was getting on I found the paper had stuck to the film so firmly that not even by washing for hours could I get it off, the result being the negative is one mass of little brown spots, precisely like a rash, which no treatment I know of has done any good. The negative being a good portrait, I am anxious to save it. Can anything be done?"—From our correspondent's letter we fear the negative is irretrievably ruined. Perhaps, however, the spottiness can be removed with a dilute solution of cyanide of potassium. This is the best remedy we can suggest.

G. FORTESCUE says: "A photographer here has taken a portrait of my minister, and is selling copies, but, as they are not marked copyright, I have copied one and am selling the prints. He is threatening to take proceedings against me, and I have written to him asking when he made the portrait copyright, and why the portrait is not marked as copyright on the mount, &c., and he declines to answer, still threatening proceedings. Can he take any?"—Certainly he can if the portrait is copyright. The owner of a copyright is not bound to answer any questions on the subject except in a court of law. Anyone who pirates a picture does it at his own risk and must take the consequences of his act. If the picture be copyright our correspondent should feel thankful to his neighbour for giving him notice to desist from the piracy instead of taking immediate proceedings.

PYRO writes as follows: "Some time ago I took the negative of a friend who gave me permission to sell copies of his portrait. Of course when he gave me this permission he expected that those who bought them would put the portraits to their legitimate use, by placing them in their albums, &c. One day a man came in and bought one, but instead of putting it to this use he has had a transparency made for the lantern, and he now uses the transparency for the purpose of throwing ridicule upon my friend. As I did not take out a copyright of the portrait I cannot prevent the man from having it copied, but can my friend make him desist from exhibiting his portrait. He objects to the exhibition, and has written me asking if the law would not compel the exhibitor to withdraw it on his writing to him and demanding its withdrawal. If so, and he does not withdraw it, what course should my friend pursue to compel him to cease this exhibition?"—So far as we can see, the only remedy is by injunction from the Court of Chancery. We are not sure that one would be granted, but no doubt it would if the aggrieved party could show that it held him up to ridicule or caused him annoyance. A respectable solicitor should be consulted.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The ordinary meeting of this Society for April will not take place on the usual second Tuesday, but on the third Tuesday, April 19.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Excursion on Easter Monday to Maidenhead. The train leaves Paddington at six minutes past ten a.m. Members will meet on the departure platform.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, April 13, 1887, will be *The Development of Drop-Shutter Exposures*. The Bank Holiday outing will be at Radlett, from Moorgate-street and St. Pancras, returning from Barnet.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1406. VOL. XXXIV.—APRIL 15, 1887.

GELATINE PLATES FOR COPYING LINE SUBJECTS.

OFTENTIMES the photographer is called upon, perhaps at short notice, to copy a document or plan which is wanted as evidence in the law courts, and in connection with which no time must be wasted. In these days of the almost universal employment of gelatine plates, he probably finds himself somewhat at a loss how to proceed in order to obtain a moderately fair representation of the original, for though for such purposes a great amount of artistic and technical excellence is scarcely required in the reproduction, still, with the general run of rapid gelatine plates and development modified within usual bounds, it is difficult to produce anything which will satisfy the photographer that he is doing justice to his client.

We know several professional photographers in whose way occasional commissions of this and kindred sorts fall, who keep a silver bath and collodion always at hand for such occasions, but we all know that a bath only used at rare intervals or by fits and starts is very liable to be found to be out of order just when required. The carefully prepared operator is thus as likely to find himself as really unprepared as he who gives no thought to that class of work. To doctor the old bath or to make a special new one are remedies which scarcely commend themselves to a man in a hurry, and he is therefore almost driven to do his best with the other means at hand—gelatine plates.

Of course it is quite possible to prepare gelatine plates for the special purpose which will give results in black and white quite equal to wet collodion, and which may be used for the most difficult of tasks of the sort, namely, the production of negatives for "process" work. But such plates are less likely to be found in the ordinary studio than collodion and bath. Besides which, we are not aware that any of the plate manufacturers at present turn their attention to plates of this description, and few professional photographers, or even photo-etchers, are likely to lay themselves out for their preparation, preferring to resort to the old bath.

This latter is, we believe, almost if not universally employed for all "process" work, and yet the importance of being able to use gelatine plates is to the photo-etcher almost inestimable. How often has a negative to be made at a time of day, at a season of the year, or under weather conditions, when even the best wet plate is almost useless, though gelatine with its greater rapidity would do what is required if only the necessary density could be obtained. Even the comparatively slow plates specially prepared for density would prove immeasurably superior to wet plates if they were but at hand, but if the

ordinary "rapid" or "instantaneous" films could be utilised, the benefit would be still greater. A method of development which provides this *desideratum* must therefore be of value.

The ordinary methods of treating a rapid gelatine film when more than usual density or contrast are required are scarcely applicable, except to a limited extent, for our present purpose. Increasing the strength of the pyro solution produces the desired effect with most plates when ordinary half tone subjects, whether portrait or landscape, are in question; but the effect is not pronounced enough to be of much value where the extremes of clear glass and absolute opacity are required. Increasing the proportion of restrainer with or without a modification of the exposure will have a decided influence in increasing density, as well as contrast for half tone subjects; but in the reproduction of fine line work, it not only loses its effect in that direction if pushed beyond a certain point, but the transparent lines of the negative are filled up by the lateral spread of the development. Bromide of potassium (or other soluble bromides) employed as restrainer retards development in a surprising degree up to a certain point, especially when employed in large proportion; but a time comes when, no matter what the strength of the restrainer, it appears to entirely lose its influence, and the less exposed, or even unexposed, portions of the film become amenable to the reducing action of the developer, and are in technical language "fogged." This limits the application of bromide to the purpose under notice, though with the usual classes of subjects in cases of over exposure, or when more than ordinary contrast is required, the practice is a safe one.

Casting about recently for some means of acquiring density with a batch of extremely rapid plates, which proved quite useless from the extreme thinness of image, we resolved to try the effect of gallic acid as restrainer in the manner recommended some two years or more ago (vol. xxxi., page 501). It was found that gallic acid, when used in conjunction with alkali, not only possessed no developing power, but when added to alkaline pyro behaved as a most powerful restrainer, far more powerful than bromide in retarding development, but without the same effect on exposure. The experiment was made with a fair amount of, though not with absolute, success, so far as the particular sample of plates were concerned; but receiving about the same time an inquiry on the subject of density in line negatives our attention was diverted in that direction, and the following is the result of our experiments.

We may premise that plates of several different makes were used, and the modified treatment produced results that varied

directly with the normal characteristics of the individual plates. Thus plates which naturally gave density with tolerable ease were affected to a greater extent than those whose tendency laid in the direction of delicate images. Thus Rouch's and Edwards's plates proved more amenable to the gallic acid treatment than Wratten's "drop" shutter" and Paget's, though both the latter gave results quite suitable for ordinary line work, though not dense enough perhaps for photo-etching or lithographic work.

In the first experiments the ordinary developer recommended with each plate was employed, only substituting for plain water a one-grain solution of gallic acid. The difference here was chiefly confined to a very considerable prolongation of the time of development, without anything like an adequate accession of density, though certainly there was a difference in that respect, and more especially in the clearness and crispness of the transparent lines.

The changes were rung upon many modifications of this treatment; the proportions of pyro, bromide, and ammonia, were varied, as well as the strength of the gallic acid. The exposures were also considerably lengthened; but though all these modifications produced a corresponding influence upon the result, still the prolongation of the time of development was the most noteworthy feature, and out of all proportion to the benefits derived from the treatment.

We next tried soaking the plate previous to development in solution of gallic acid, and this proved a decided advantage. A three-grain solution of gallic acid was made and filtered, and into this the plate was plunged for half a minute upon removal from the dark slide. One minute and two minutes were first tried, but the shorter period of thirty seconds proved sufficient. Upon removal from the gallic acid bath the plate was immersed, without washing, in the developing solution. This was composed at first according to the instructions issued by each maker, but eventually we found that under the circumstances these formulæ were by no means the most suitable, what was required being a solution strong in alkali and well restrained.

Accordingly we settled upon a universal formula for all plates, containing in each ounce of developer three grains of pyro, three minims of ammonia, and five minims of a sixty-grain solution of bromide of potassium. In this solution the plate remains for a very considerable time before any appearance of development is discernible, probably three or four minutes, after which the image appears very gradually and with beautiful clearness. If there should be any reluctance on the part of the lines in the darker portions of the engraving to come out, we added more ammonia, and as soon as the details in such portions were strongly impressed the quantity of bromide was doubled. These details were adhered to with the exception that the gallic acid solution was reduced to two grains to the ounce, and the results were such as to fully satisfy us in most cases. With some plates, however, it was found necessary to force the quantity of ammonia so greatly that, though no signs of surface fog were visible before fixing, green fog was apparent to an alarming extent after that operation had been performed. The density even with the feeblest plates was all that was required for ordinary line work; but with those which easily run to density under ordinary circumstances absolute opacity was readily obtainable, but the operation was a slow one, lasting at least twenty minutes.

With a view of avoiding green fog, and also in the hope of hastening the acquisition of strength, we resolved to try the

substitution of potassium carbonate for the ammonia, since, as is well known, the carbonates do not produce green fog, while by increasing the strength of the solution density is promoted, and, moreover, they can be employed without bromide, and consequently the development is shortened. The results more than bore out our anticipations. Not only was the time of development reduced to one-third, but a still greater degree of density was most easily attained, and the finished negatives were entirely free from green fog.

The following developer we found to answer with *all* kinds of plates, except such as possess a tendency to "frill," and we are sorry to say that such a tendency developed itself in two brands of plates we had not hitherto suspected, and which, with the potash developer, proved perfectly incurable:—

Potassium carbonate	360 grains.
Sodium sulphite	360 "
Water	6 ounces.

To each ounce of developer two drachms of this solution, together with thirty or forty minims of the ordinary ten per cent. solution of pyro (and sulphite), were added. The mode of development we found to answer best was to soak the plate first of all in the gallic acid solution for thirty seconds, and then to transfer it direct to the developer, where in another half minute or so the image commences to appear. Watch carefully, and when the details in the darkest parts of the engraving acquire tolerable strength, add five minims of a sixty-grain bromide solution and go on until sufficient density is acquired. Should matters hang fire at all, a few drops of the ordinary dilute ammonia solution may be added to freshen up the developer, but this will rarely be needed if the exposure has been correct.

On the latter point a word may be said. Though the use of gallic acid does not necessarily lengthen the exposure required, we find it better to give more than is *absolutely* necessary. Thus, if five seconds be sufficient to produce a perfect image under ordinary circumstances, give ten, or even fifteen. The result will be quicker development, less necessity for forcing, and hence less chance of fog, stain, or filling up of the lines. Six times the normal exposure has not produced any signs of the plate being over done; indeed, it seems next to impossible to produce such a result when the gallic acid is employed in this manner.

DISTEMPER BACKGROUNDS.

In a previous article we gave practical details for producing plain backgrounds in flatted oil colour. We shall here describe the method of preparing them in distemper. Ordinary distemper backgrounds, it may be explained, are easier of preparation by the novice than are those in oil colour, while they answer the purpose equally as well. They have, however, the disadvantage of not being so durable, though this, to some extent, is compensated for by the ease with which they can be recoated in case of injury.

Premising that the background is to be a new one, and that the work has to be commenced *ab initio*, the first thing to do is to strain some canvas, or sheeting, on to a frame or wall as described a fortnight ago for oil colour, the same kind of fabric being employed. Next it is coated with size, as then directed, when it will be ready for the distemper.

The distemper is prepared as follows. Dry colours, as supplied by the oilmen, are mixed with warm water to about the consistence of thick cream. The colours selected must, of course, depend upon the tint desired. A grey is made by mixing

common whiting with lampblack—an addition of Venetian red will give the grey a warmer and more agreeable tone. Burnt umber and whiting, with or without the addition of black, also makes a pleasing colour for a background. But the particular colour adopted is, in all cases, very much a matter of taste on the part of the operator. When the colours, whatever they may be, are intimately mixed and rendered free from lumps, a quantity of common size—procureable at the oilshops—is added, and the whole well stirred together. It is scarcely necessary to say that the size must be melted before it is added. The object of using hot water in mixing the colours is to prevent the size from gelatinising on its addition.

With regard to the quantity of size and the amount of colour to be used, no definite proportions can be given, as all will depend upon the pigment selected, some being much heavier, in proportion to their colouring power, than others; also upon the fact that different samples of size vary much in their strength. One or two experiments will determine this point. There is, however, great latitude in the matter. The effect of too little size is that the colour will rub off when dry; and of too much, that the work will dry with a gloss. Some criterion as to the proper proportion is this: when the mixture is cold it should form a thin tremulous jelly. After the right proportion of size has been added and thoroughly incorporated, the whole must be strained through coarse muslin or fine canvas. It is then allowed to become perfectly cold—prepared one day it will be ready for use the next.

The great point in connection with the use of distemper colour is to employ it cold and in a jellied condition, because if it be used warm it is very difficult to obtain an even surface free from brush markings. Sometimes a small quantity of treacle is added to the mixture. The object of this is to prevent the coating, when dry, from becoming brittle, and eventually peeling off or cracking should the background require to be rolled up. It also somewhat retards the colour from drying, which is often an advantage when it is applied during hot weather. If this addition is made the old-fashioned "green treacle," or molasses, should be employed, and not what is known as golden syrup, which is quite a different thing. When the distemper mixture is firmly set it is well stirred up with a stick, so as in some measure to break up the jelly. It is then ready for use.

The colour is applied to the canvas with a common white-wash brush. It is laid on somewhat thickly—the small lumps of jellied colour being broken up with the brush as it is applied. It is not necessary that the distemper be laid on so evenly as it is in the case with oil colour, for so long as no actual lumps remain it will suffice. A distemper background may look exceedingly unpromising when it is partially dry, but yet prove perfectly even when quite so. The chief thing with distemper—as with flatted oil—is to avoid one portion of the work becoming dry, or partially dry, before the next is covered. Unless this be accomplished the overlapping brush marks will invariably be apparent in the finished background.

One point in connection with the avoidance of brush markings is that the ground should be rendered impervious in the first instance, otherwise, when the colour is applied, much of the moisture it contains will be immediately absorbed by the fabric itself, thus leaving the surface of the colour in a semi-dry condition.

In the foregoing directions we have assumed that a new background was being dealt with, but it will often happen that an old one has to be treated. In this case there is no material

difference in the *modus operandi*. The old background must be sized the same as a new one in order to render it non-absorbent. If it has already received many coatings of distemper there will, necessarily, be a considerable accumulation of colour on the fabric. This excessive thickness of pigment will always have a tendency to crack in very hot weather, arising from the contraction of the old gelatine present. This tendency may, to a great extent, be counteracted by introducing some substance which will prevent the colour from becoming abnormally dry. Treacle will fulfil this condition; therefore, to the size used for the sizing prior to recoating, a small quantity should be added. The mixture of size and treacle being absorbed by the accumulated pigment will confer upon the film a certain degree of flexibility as well as elasticity. Care must, of course, be taken that an excess of treacle is not employed, which would prevent the colour from drying at all.

A PRELIMINARY account, by Dr. Arthur Schuster, of the photographic results achieved by his division of the observing party during the eclipse of last August, has been read before the Royal Society, and contains matter as interesting to the photographer as it is valuable to the astronomer. Unfortunately the weather, as has already been said, was by no means favourable, so that all the original plans for attacking the eclipse phenomena had to be modified at the last moment. The length of the exposures, for instance, had all been arranged beforehand; but the weather was so uncertain that they had to be instantaneously estimated at the exact moment of "uncapping" in each case. One consequence is a little uncertainty as to the actual duration of the exposure, Dr. Schuster's belief being that they were from fifteen to twenty seconds. The definition he obtained in the negatives was not entirely satisfactory; and after a most careful examination of the different adjustments he came to the conclusion that it did not lie in the photographic process, but "if we are to obtain better photographs of the corona, we can only hope to do so by means of a better mechanical arrangement for moving the camera." We learn from this preliminary account that a paper negative was attempted, but that it showed only very little detail, although the glass negatives gave definition equal to the Egyptian eclipse pictures. He had three cameras at work, one for direct photographs and the others for spectroscopic observations. One of the sets of plates had been specially prepared by Captain Abney to be sensitive to green radiations.

SOME time ago we brought under our readers' notice a description of Professor Langley's bolometer, an instrument strongly sensitive to the invisible radiations of the infra-red even when of great feebleness; but at the same meeting that the above-mentioned paper was read, Mr. C. Vernon Boys described an instrument he had devised which was far more sensitive than even the marvellous bolometer. So sensitive is it to radiations of slight intensity that, even in an imperfect form, the "radio-micrometer," as it was called, was capable of giving indications when subjected to the radiations emitted from a halfpenny when illuminated by a candle at a distance of eleven hundred and sixty-eight feet! The inventor stated that it could easily be shown that the instrument would be sensitive to a change of temperature of the one-hundred-thousandth of a degree of heat.

AN instructive experiment was shown before the Berlin Physical Society by Dr. Vogel, with the idea of disproving in an effective manner the exploded, but still popularly held, theory, that a mixture of blue and yellow lights gives a green colour. The experiment may be here detailed, as it has a most instructive bearing on certain notions about dark room windows, held even yet by some workers. Many photographers still believe that if one thickness of glass of a certain colour will not suffice to arrest the fogging tendency, a second sheet in front of the first is found to do it. They entirely disregard the fact that the eye alone is not for one moment to be trusted to gauge

the quality of any colour for photographic purposes, as a residuum of strongly actinic light may yet pass through a medium that appears of the purest orange or red, and that that residuum will pass, but slightly diminished, through a similar sheet. Dr. Vogel's experiment brings this fact home in a very conclusive manner. He filters the light, first, through a layer of a solution of "acid yellow" (picric acid, probably), the issuing beam being then of a bright yellow. When he allowed this light to pass through a phial containing an ammoniacal solution of copper (a vivid blue in colour) a bright green appearance was produced; but when a phial of similar blue appearance, but different chemical nature (aniline blue), was placed in the path of the yellow rays, the difference was most striking; instead of green a fiery red colour was seen.

A KNOWLEDGE of the constitution of colour is a necessity for all photographers who look upon photography from its scientific side, and the principles elucidated by the above experiment might be indicated in many other ways. There was recently described in *Nature* a very neat way of mixing colours by superposition by means of the optical lantern, one light and lantern only being required. The ordinary objective was replaced by a frame containing a lens cut in two, the halves being made to slide to and fro. Each half acted as a lens, so that when placed together the image of the light, as seen through a small circular diaphragm, was projected as one disc on the screen, but by sliding the lenses in contrary directions, discs overlapping one another to any extent might be obtained. To mix colours all that was necessary was to place coloured films, or troughs of coloured liquids, behind each half of the lens, and upon the screen they would be respectively separate and mixed to any required extent. We commend this simple plan to the notice of photographic lantern exhibitors.

Just at present the possibilities of the great Lick telescope are greatly occupying the minds of scientific observers in America, and, near the scene of its operations, an acrimonious newspaper war is being fought upon the question. Mr. Proctor has been pointing out that, hitherto, big telescopes have, almost universally, been a practical failure, so far, that is to say, as regards what might be reasonably expected from them; hence he would appear to infer that the new instrument is also likely to be classed among the useless tubes, and he has raised rather a storm at San Francisco. After all, there are no grounds for asserting that because one big telescope fails another will also, so that we still hope to hear of some marvellous photographs being obtained by this monster instrument.

Our readers may remember that Mr. Howard Grubb had, for use with the telescope, designed an improvement upon the ordinary observing chair, which may be more properly termed a ladder, but that his design was stated to be too late. We learn, however, from Professor Holden's paper in the *Atlantic Monthly*, that the plan is to be adopted. An observing chair for this mighty instrument would need to be of any height from five to thirty-five feet, but Mr. Grubb, instead of allowing the observer to be put to the trouble of what would practically be like ascending the stairs of a lofty house each time he went to observe, uses a chair of ordinary dimensions, and enables the observer to reach the eye end of the instrument by raising or lowering the whole floor of the dome at once. This moving floor is to cost fourteen thousand two hundred and fifty dollars—nearly three thousand pounds.

THE OXYHYDROGEN ZIRCONIA LIGHT.

ONE or two readers of the JOURNAL may possibly remember that a year or more ago I was very anxious to avail myself of, and to obtain for the use of others, the alleged advantages of the Zirconia light. According to what had been written about it, we were in this way not only to avoid pitting of the lime, but the rarer earth was also considerably the "most luminous." I am sorry to have to report only a failure so far, and that of a kind which practically puts an end to my own expectations of any good result. It is with a last hope of eliciting any better results from others, that I now briefly state my experience.

During the last twelve months I have seen several statements in various papers that Zirconia was "frequently" used instead of lime; but every effort on my part to find one such operator, who was actually using this earth, has proved fruitless. Equally fruitless have been my endeavours to procure one of M. Tessie du Motay's Zirconia pencils, such as were sold years ago, and exhibited once at the Royal Institution by Mr. Ladd. The successors in business of that gentleman are unable to assist me, and I cannot get such a thing anywhere. If any reader possesses, and can lend me, one of these pencils for a brief trial, I shall feel particularly obliged to him.

I have myself tested experimentally three different samples of Zirconia; and as my sole hope of ultimate success lies in the fact that each one of the three behaved in a different and distinct manner, and therefore that the removal of the presumed impurities might improve the results more than I expect, I describe them.

1. The first was a sample considered "pure" by Messrs. Hopkin & Williams, kindly compressed for me, and for his own trial, by Mr. Chadwick; but this sample was so impure as to be useless after about a quarter of an hour. It coloured the flame intensely yellow, and the prism at once showed this to be due to a considerable portion of soda. Otherwise, the incandescence itself was pretty white (as distinct from what is mentioned presently), and the soda might in time probably have been volatilised out of the cylinders. A far worse fault was the large quantity of silica in the sample, which quickly fused into a thick yellow glaze, in which large cracks immediately appeared. After that the light was far too poor for any purpose, and was not good at the best. I may say that all the samples were tried on the flat ends of cylinders about three-eighths of an inch in diameter, giving a bright disc of that size.

2. The next sample or samples were prepared (largely by blowpipe process) by a gentleman who does not wish his name mentioned at present, but who has taken great interest in this matter. There was not much soda in his samples, and it rapidly disappeared under the jet. The sample also stood the jet much longer and better. But considerable silica (the great difficulty in preparation) remained, and through dark glasses could be seen to seethe and fuse under the heat, rising into waves and ridges. After this the light diminished very greatly, and great cracks appeared in the face of the cylinder. There began now, moreover, to appear a peculiar reddish glow about the light, utterly different from the sodium flame, and quite pronounced; and the peculiar properties of Zirconia were now very conspicuous, especially as regards its extraordinary *non-conducting* character. With a powerful jet playing on this small surface, the incandescent portion only extended about one-tenth of an inch back from the face, and was bounded by a nearly sharp line. Moreover, the bright surface barely extended to the edge of the small disc, and the brightest portion in the centre was only three-sixteenths of an inch in diameter. A further curious phenomenon was, that the cylinder rapidly began to crack all round at the boundary of the bright incandescent portion, and this crack gradually penetrated the cylinder till the slice thus separated fell away from the face. This seems to show a sudden and unequal shrinkage, which I fear will be a great difficulty in using Zirconia. This light, at its best, was considerably inferior to that from an ordinary lime with the same jet.

3. The third sample was obtained by Mr. H. G. Madan, of Eton College, from Herr Schuchardt, of Görlitz, and was stated to be prepared "especially" for the oxyhydrogen light. It is sold at the rate of eighteen shillings for ten grammes, of which about half is needed for one small cylinder. This powder shrank enormously when heated, showing that the oxide was very largely hydrated, and that the water was driven off when the cylinder was ignited. Otherwise the sample appeared the purest of the three, was very dry after ignition, and the cylinder was much more friable or fragile after compression. (The preceding samples were both as hard as marble after delivery from the die.) On heating in the jet, however, the plug seemed to *bake* quite hard. It behaved quite differently from either of the others, being evidently far more free from silica. After half an hour there was nothing on the face beyond a very slight and even glaze—no mass of glazed silica, as in the others, and the surface remained flat and sound. But the red glow was far more marked than in either of the two former, and I am most anxious to discover whether it is characteristic of pure Zirconia itself, or is due to some impurity which might be.

eliminated. Also the circular crack round the cylinder was formed far more rapidly than on the others, and the layer on the face dropped off after no more than half an hour. I much regret that this separated layer was not inserted in a loop of platinum wire, and heated by itself, as such a thin disc might possibly not crack again.

But the light was, again, far inferior to that of a lime. Mr. Madan tested the plug again, after being crushed and remade up, at Eton, and compared the lights photometrically in the usual way. With the same jet, the light from the end of the Zirconia cylinder was to that of an "Excelsior" quarry lime in the proportion of 1 : 2.88. This is a very startling difference, and the opinion of all who have had to do with these experiments, is very decidedly to the effect that the vaunted Zirconia light is what Americans call "a fraud."

Some qualifications may, however, be made. The surface made incandescent upon a lime cylinder is obviously much larger than that of a disc three-eighths of an inch in diameter; in fact, probably the proportion is not very different from that of the illumination as given above—hence the *specific* brilliancy of surface may be about the same, or a little more. It may be asked, Why, then, not use more surface of Zirconia? As regards any single jet, the answer is, that owing to the extraordinary non-conduction of heat before alluded to, such larger surface *cannot* be illuminated. The gentleman whose name is not mentioned is about to try the experiment, however, of using upon a larger disc the flame from two or three nozzles, and I await the result with interest. This will, however, even if successful, lose one of the best properties of the Zirconia light. The *small* bright disc gives a parallel or other beam from the lantern, for optical work, about as "sharp" as from the electric arc. So great is this advantage for some purposes, that if I could only obtain cylinders that would "stand," free from silica, and which did not crack off, I would be thankful for them even with the less light: with the microscope, for instance, the light condensed on a slide for a one-eighth immersion lens would be nearly as great, and the definition better. It is chiefly on this account that I ask for any information any one can afford on the subject of Zirconia.

It may naturally be asked, How does it happen that our experience, as here narrated, differs so radically from that stated by others as regards the "superiority" of this light? My own opinion is, that the American and Continental experimenters simply have not known *what a good limelight is*. Professor Linnemann's new jet, which has been recently described, has the very useful property of condensing the heat into a very small point—very valuable for spectrum purposes; but otherwise it is only a blow-through, and when he remarks on the "unsteadiness" of the light from other forms, he shows at once that he has not worked with the right thing. Several Continental jets have come into my hands at different times, not one of which would give a good light in the opinion of any ordinary English lecturer, and the Americans, also, are fond of jets with extremely small apertures, judging from some I have seen. It is noticeable that with an ordinary and fairly good *blow-through* jet the Zirconia compares with the lime much more favourably; it seems to give a much greater proportion of light when so heated than the lime does, as if it became sooner "saturated"—if the expression may be employed. That is the only explanation I can suggest.

However, I am most anxious still for *any* further information any one can give. I am particularly desirous to know, as to details, (1), Whether the peculiar *red glow* is characteristic of Zirconia itself, or of some impurity. (2), Whether there is any source whence it can be procured commercially, thoroughly *dehydrated* and *freed from silica*. I know Dr. Draper's process, but have not time or means to think of preparing a sample myself, nor am I anything of a chemist. And, (3), whether any one has had experience of a sample which does not crack off in the way described, or found success in using a *thin slice* in the way suggested, but which we have not tried as yet.

LEWIS WRIGHT.

P.S.—*Arc Light*.—I should be very much obliged if Mr. McDougall would state particulars of the arc light used at Dundee, as described by him, namely, the lamp employed and the current used, stated in volts and ampères. His electrical friends would give him these details, for which others would thank him as well as myself. At the same time I am not so sure as he seems to be that the oxyhydrogen light would have utterly failed on a thirty-feet disc, especially if there

really is any superiority in it when bottles are used. I fancy the old Polytechnic screen was not much, if any, short of that. I know no thirty-feet screen in London now, or one or two of us might rather like to have a shot at it, just out of curiosity, to see what *could* be done. I am not sure but a one-tenth of an inch nozzle and ten feet of oxygen per hour might do decent work. My interest in that point is, however, purely speculative. I fully agree in the superiority for all practical purposes of the arc for large screens, and have present practical reasons for asking for his details.

L. W.

A SHORT HISTORY OF PHOTOGRAPHY IN COLOURS.

THERE is probably only one thing which it is safe to predict about the problem of obtaining permanent photographs which shall represent objects in their natural colours, and that is that the discovery, if it is ever made, will not be the result of an accident. The question must be studied and the conditions mastered before the attempt can be made with even the least chance of success. The following account is given with the hope of drawing attention to the progress which has already been made, whence it will be seen that, with regard to naturally coloured pictures, we are now precisely in the position occupied by Davy and Wedgwood with respect to ordinary photographs at the commencement of the present century. Davy could obtain copies of objects upon paper coated with silver chloride (1802), but he could not fix them. Similarly it has been possible for many years, certainly since 1848, to obtain naturally coloured photographs; but no certain means have yet been discovered by which they can be rendered permanent. The colours fade away when the pictures are exposed to light, or when they are treated with the ordinary "fixing agents" of the photographer. When will the Niepce, the Talbot, or the Daguerre arise who will do for colours what these "fathers of photography" did for pictures in black and white?

Seebeck's Experiment, 1810.—Early in the present century an observation was made which favours the views of those who believe in the possibility of reproducing, photographically, the natural colours of bodies. In 1810 Dr. Seebeck, of Jena, was engaged in repeating certain experiments, first made by Ritter in 1801, upon the existence of the ultra-violet rays. For this purpose Seebeck passed a beam of white light through a prism, and received the spectrum, or band of coloured light so produced, upon a sensitive surface of chloride of silver. Upon this substance he was afterwards surprised to see distinct traces of colour. Describing the experiment in the *Farbenlehre* of Goethe, Seebeck writes:—"When a spectrum produced by a properly constructed prism is thrown upon moist chloride of silver paper, if the printing be continued for from fifteen to twenty minutes, whilst a constant position for the spectrum is maintained by any means, I observe the following:—In the violet light the chloride becomes a reddish brown (sometimes more violet, sometimes more blue), and this coloration extends well beyond the limit of the violet. In the blue part of the spectrum the chloride takes a clear blue tint, which fades away, becoming lighter in the green. In the yellow I usually found the chloride unaltered; sometimes, however, it had a light yellow tint. In the red, and beyond the red, it took a rose or lilac tint. This image of the spectrum shows beyond the red, and beyond the violet, a region more or less light and uncoloured."

Observations of Herschel, Daguerre, and Talbot.—In 1833 Sir John Herschel also noticed the colours produced upon sensitive surfaces by the action of coloured light. He found that "the spectrum impressed upon a paper spread with the chloride of silver is often beautifully tinted, giving, when the sunshine has been favourable, a range of colours very nearly corresponding with the natural hues of the prismatic spectrum. The mean red ray leaves a red impression, which passes into green over the space occupied by the yellow rays. Beyond this a leaden blue is discovered."

Daguerre noticed that a red house gave a reddish image on his iodised silver plates in the camera, and at an equally early date Fox Talbot observed that the red portions of a coloured print were copied of a red colour on paper prepared with chloride of silver.

Hunt obtains Photographs Coloured by Light.—Between 1840 and 1843 Robert Hunt tried many experiments on the production of coloured images by light. By dipping paper first into nitrate of

silver, and then into sodium fluoride, he obtained a thin coating of silver fluoride. When this paper was exposed to the spectrum "the action commenced at the centre of the yellow ray, and rapidly proceeded upwards, arriving at its maximum in the blue ray. To the end of the indigo the action was pretty uniform; it then appeared to be very suddenly checked, and a brown tint was produced under the violet rays, all action ceasing a few lines beyond the luminous spectrum. The colours of this spectrum are not a little remarkable. I have now before me a spectrum impressed two months since, and the colours are still beautifully clear and distinct. The paper is slightly browned by diffused light, upon which appears the following order of colours:—A yellow line distinctly marks the space occupied by the yellow ray, and a green band the space of the green; through the blue and indigo region the colour is an intense blue, and over the violet a ruddy brown." Although this description is not very clear, it seems to point to two modes of treatment of the sensitised paper. The colours were only obtained in the second case, when the paper had been insulated or exposed to light for a short time before the spectrum was allowed to fall upon it.

Other results obtained by Hunt are recorded as follows*:—"A paper prepared by washing with barium chloride and nitrate of silver, allowed to darken whilst wet to a chocolate colour, was placed under a frame containing a red, a yellow, a green, and a blue glass. After a week's exposure to diffused light it became red under the red glass, a dirty yellow under the yellow glass, a dark green under the green, and a light olive under the blue."

In another experiment, tried in 1843, with paper prepared with bromide of silver and gallic acid, "the camera embraced a picture of a clear blue sky, stucco-fronted houses, and a green field. The paper was unavoidably exposed for a longer period than was intended—about fifteen minutes. A very beautiful picture was impressed, which, when held between the eye and the light, exhibited a curious order of colours. The sky was of a crimson hue, the houses of a slaty blue, and the green fields of a brick red tint." Hunt adds, "Surely these results appear to encourage the hope that we may eventually arrive at a process by which external nature may be made to impress its images on prepared surfaces in all the beauty of their native coloration."

W. JEROME HARRISON, F.G.S.

(To be continued.)

ON THINGS IN GENERAL.

MR. ARTHUR DEBENHAM has raised a nice point (or has had it raised for him by a client) in an inquiry as to whom a negative belonged to. It is, however, not to be settled in the jejune manner of one correspondent who replies to his letter. It would be a very simple matter to clean a negative with a hammer if a doubt as to its ownership were raised; but in the event of the sitter "going to law," and the ownership being decided to be vested in the other side, the owner of the hammer would be in an awkward position. As to the moral aspect of the question, there can be little possibility of conflict of opinion; but its legal bearings might present much difficulty. To the best of my recollection, the question has been raised on more occasions than one in years gone by—twenty or thirty years ago—but I do not remember a case having been brought into court. In those days there might be some excuse for the sitters claiming the "plate," when the artistic qualities of most photographs were at such a very low ebb that there was some justification for the analogy then suggested—"twenty-five address cards, including plate, for half a crown." But at the present time when men of great artistic power produce photographic portraits, and much skilled artistic labour, in the shape of retouching, is bestowed upon a negative, it would be the height of injustice to claim the negative from the photographer. Still, it is, after all, a point of law upon which a layman could not give any opinion of value. My view as to the result of an appeal to law is that all would depend upon the skill of the lawyers employed to get up the case. If there were a readier means of obtaining copyright, say, for example, as suggested by "Artist" in a recent number of this JOURNAL, much of the difficulties of such matters would disappear, though it is obvious that to make every picture copyright

that a photographer takes would be entirely out of the question. A rather amusing lawsuit connected with this branch of the question was tried the other day. A very Great Personage was standing at the front door of a gentleman's house, and the house and the Great Personage were photographed. The owner of the house asked for and obtained an injunction to restrain the photograph being published by some one into whose hands it had got. I should very much like to see a copy of the "little bill" that will have to be paid!

The hanging at the last exhibition of the Parent Society seems to have excited an amount of acrimony and discussion greatly in excess of anything of the sort I remember. The post of "hanger" is a most unfortunate one to be thrust into, for, as one of the contributors to the recent controversy says, it is impossible for him to please every one. I consider it absolutely impossible for any one to know the real difficulties of the task who has not had actual experience in the matter, and unless he is an enthusiast no one will ever care to repeat such an experience. I was quite recently connected with an exhibition of paintings in which an irascible gentleman, who lent some eight or nine pictures of great value, absolutely, emphatically, and rudely declined to allow his pictures to remain for an extension of time that had been arranged for, simply and solely because of an insult to one of his pictures; it was couched in a low key of colour, and the exigencies of space had necessitated a rather brilliant painting, received at the last moment, being placed in immediate juxtaposition with this particular one of his paintings! The point is just such a one as was referred to by Mr. Wollaston at the meeting of the Photographic Society of Great Britain.

I was amused by Mr. Pringle's account of his visit to Mr. Valentine's immense establishment, which is evidently a place once seen to be remembered, and Mr. Pringle evidently made the best use of his eyes while going over the place. Referring to his remark that he found at least one man of like opinion as himself as to the best colour of a dark room—said colour being red—I may say that I can give another instance. Some half dozen years ago I remember being in the dark room of a well-known professional whose dark room walls were discoloured with a bright red colour.

There was a most instructive discussion at the last reported meeting of the lantern section of the Manchester Photographic Society in which the question of bottles *versus* bags was well weighed and considered. There can be no doubt that retort-made oxygen is cheaper than the bottled article, though the difference is less than appears at first sight, seeing that most calculations leave out the item of cost of skilled labour when the former is discussed. But the convenience of compressed oxygen is so very great, that it is often worth the extra cost. With regard to the pressure regulator to ensure the issuing gas always leaving at the same pressure, I would like to remind the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY that Mr. Lewis Wright, in that most valuable work of his—*Light*—describes a regulator that may be purchased for a few shillings which acts in a manner equal to the most expensive, provided that the pressure does not fall below a certain previously arranged degree. In the case of bottles this, of course, would only occur when they were becoming almost exhausted. It appears to me that the great bugbear of most people in this matter is the difficulty of ascertaining the amount of gas present. There should not really be any practical difficulty, for a simple glass gauge might be attached by means of a screw which would enable the contents to be estimated to a nicety. A still simpler plan would be to weigh the cylinders at the beginning of an entertainment—a little calculation would easily show how much gas had been used up. Heavy as is a gas cylinder, the loss of an ounce would be easily noted, and a single foot of gas weighs not far from an ounce and a quarter.

The possibility of paper support for emulsion preventing halation still seems to have many believers; indeed, I do not remember any what might be termed authoritative statement, one way or the other, having been published, though I have come across instances where what is represented to be halation has been manifested on paper negatives. One is inclined to say "Why, practically, should not halation or something like it, be produced on paper?" Paper is almost, if not quite, as translucent, thickness for thickness, as a gelatine emulsion film, and granted that an image in the shape of a strongly illuminated spot be thrown upon a piece of paper I see no reason why

* *Researches on Light*, 1844, page 277.

sufficient light should not be dispersed in a lateral direction to enable a developable effect to be produced. Can any one give a reply to this query, based upon practice? FREE LANCE.

PACKING AND HANGING PHOTOGRAPHS FOR EXHIBITION.

SINCE last year's exhibitions throughout the country a great deal has been said of the hanging and packing of the photographs sent, and possibly a little more on this inexhaustible subject might not be out of place, with the object of trying to find a better means of procedure than that we are accustomed to.

Papers recently written are full of pointed, valuable hints to exhibitors, and the recitals of exasperating fractures, notwithstanding fair precautions, are well worth further thought before the regulations for the coming season's exhibitions are drawn up.

The actual hanging of the pictures entails an amount of serious work on those members who have rashly allowed their names to be on the hanging committee. Hours lengthened into days in some cases are spent in the task. An eye for beauty! an eye for symmetry! for harmony, for effect, for honest judgment and impartiality! are these kept in view while selecting the committee? I believe they are, yet in nine cases out of ten, when the actual work has to be faced, these attributes have to be ruthlessly kept down. The pictures may be hung and rehung, striving after the best possible positions, but before much headway has been made the hanging becomes pretty much a question of fit, and to the tired workers possibly behind time and with the Secretary following up with numbered labels, forwarding the cataloguing, it requires a very glaring error in harmony to induce them to revise a portion of their work.

The pictures are not so easily coaxed into their right places, and the necessity at times of having to remove several before being able to readjust a delinquent is not pleasant. Such commands as "Let it alone or you'll have the whole lot down directly," become frequent, and the thought suggests itself, Is there no easier method than the present? The amount of manual labour should be reduced to its lowest possible limit, a means of building up the pictures and of readily transferring from one wall to another might be devised, and those who are responsible for the general harmony and effect would have more scope for displaying their artistic taste.

I commend to the notice of your readers the plan pursued by the owner of a choice collection of oil paintings lately on view in the Academy of Arts, Newcastle. No doubt it may be familiar and in vogue at many similar exhibitions of paintings, but it has not, so far as I am aware, been adopted for photographs. It may or may not be considered the right mode for such, but that it is, when uniformly carried out, no detriment to the artistic value of the exhibits is fully shown in a photograph taken of a portion of the collection alluded to, which disposes in a very practical fashion of many of the difficulties of packing, hanging, and repacking. For the convenience of carriage, and subsequently of hanging, each framed painting is screwed into a neat, closely fitting case. This effectually preserves the picture during transit from place to place. From these cases the pictures are not removed, the lid only being taken off, and it is here that the utility of the arrangement is seen, for in a remarkably rapid manner the paintings are hung by simply placing the first series right round the base of hanging space and by building the remainder upwards, one case thus acting as a shelf or support for the other. It can easily be understood how firmly and quickly these can be made secure. By this method it is a very simple matter to try the various possible positions of pictures; they can be shifted so readily and an effect pleasing to the eyes of the hangers obtained without a surplus of energetic work or tedious waiting.

From a view of the collection above alluded to, it was evident that all sizes of pictures were as readily adaptable to each other as by any other method of hanging, and as pleasingly diversified. It may be thought by some that the cases would mar the beauties of the exhibits, and attract the eye to the disadvantage of photographs, but in practice I think it would not be found so, as when all are placed merely the edges of the cases are visible, and these could be painted a dark, unobtrusive colour, and would act just sufficiently as a distinctive line between exhibits, and prove, in many instances, a setting to the framed photographs. If such a course as here advocated were to become general, if a rule were made that all exhibits were to be forwarded fitted closely into a case of an approved description to be used as described above, how much simplified would be the management of our exhibitions. The amount of space, for instance, could be fore-calculated to a nicety, and provision made in the shape of

temporary screens to supply extra hanging space if convenient, and when known to a certainty they would be required.

Another important result would be the lessening of breakage. I cannot see how, except by downright, almost wilful, carelessness, any picture could get damaged. There would be no unpacking in the ordinary sense of the term, for the photograph would remain in the case. The lid only would be unscrewed and fixed on behind, and ready when wanted at the close of the exhibition. It is often in getting the frame out of its packing box that fractures occur, and valuable exhibits either patched up to their disadvantage or put aside as irremediable. In many instances, too, the exhibition room is not available for unpacking, some other part of the building, or neighbourhood, is used, to the further risk of damage in transit of the unprotected frames. These and many other liabilities of fracture that need not be enumerated would be avoided.

The trouble, and often expense, of storage of empty cases would also be a thing of the past, as there would be no empty cases to store. An exhibitor would gain renewed confidence if the plan suggested were adopted, as not a few have sworn off exhibiting in consequence of annoying scratches and fractures. T. M. LAWS.

FIXING SILVER CHLORIDE PRINTS BY MEANS OF SOLUTION OF AMMONIA.

[A Communication to the Edinburgh Photographic Society.]

To the usual mode of fixing photographic prints by means of hyposulphite of soda there are two leading objections: the first is the thorough after washing required, necessitating the expenditure of much time and water to get rid of the hyposulphite of soda and silver; the second is the doubt that overshadows the process as to the permanency of the prints even after all this trouble. To eliminate this second objection, various oxidising agents have been proposed, such as the peroxide of hydrogen, chlorine, &c., to destroy the last traces of the hyposulphites; but these are, I believe, seldom employed. At any rate, the first objection is so formidable as to make it desirable to escape from it.

Several substitutes for the hyposulphite of soda as fixing agents have been advocated. The sulphocyanides were extensively used in 1867 by M. Civiale, and again, in 1874, by M. Cayol; and in THE BARRIST JOURNAL PHOTOGRAPHIC ALMANAC for this year, the use of sulphite of soda is advised and described by Captain Abney.

Although the solvent powers of solution of ammonia have been known since the infancy of chemistry, I am not aware of any serious attempt having been made to use it as a practicable means of fixing the paper prints. Mr. Hume has obligingly directed my attention to Professor Hunt's *Photography*, and I find in the edition of 1851 the author says, "The chloride of silver being soluble in solution of ammonia and some of its salts, they have been recommended for fixing photographs. The ammonia, however, attacks the oxide, which forms the darkened parts so rapidly that there is great risk of its destroying the picture, or, at least, of impairing it considerably. It matters not whether the liquid ammonia or its carbonate be used, but it must be a very diluted solution. The only photographs on which I have used it with any success are those prepared with phosphate of silver, and to these it imparts a red tinge, which is fatal to their use for transfers." In the edition of 1857, I understand, he adds the following remark, "Still ammonia affords a ready means of partially fixing a photograph, and thus preserving it until a more convenient period for giving it permanence."

These statements were not encouraging, and I fancy may have had much influence in staying further trials. As my experiments with ammonia fixing have, so far as yet tested, had very satisfactory results, I can only account for its non-employment to some prejudice, and to the very unsatisfactory appearance of prints treated by ammonia when these are not toned at all, or only moderately so, with chloride of gold. I find when the gold toning is pushed far enough—that is when the picture has, in a considerable degree, been converted from a silver into a gold one—that the appearance after fixing in ammonia, whether a weak or a strong solution be used, is in most cases pleasing.

There is no difficulty in removing the uncombined chloride of silver from the print—this seems to be very soon eliminated—but a more prolonged treatment with the ammonia is required to get rid of the organic compounds, or compound of silver, resulting from the presence originally of the two salts, chloride and nitrate of silver, and the two organic substances, paper and albumen. If left in to any considerable amount, this leads to ruddy orange stains, or feeble general tinting produced when the print is exposed to sunlight. When, however, a little only is retained in the print, that may assume a nice cream colour, very suitable for some subjects, and it remains for time to determine whether any objectionable after changes may arise from its presence.

I am myself so hopeful of the good behaviour of prints fixed by ammonia, that I have in the meantime laid hyposulphite aside, and may be able to report at some future date the effects of subjecting some of these to the evil influence of a damp cellar, or other adverse conditions.

I have experimented on the solubility of chloride of silver in ammonia—somewhat roughly, I admit—and have arrived at a much higher rate of solubility than given in the only quantitative statement I have met with. I find that two per cent. solution of ammonia dissolves more than four grains per ounce, or a weight of chloride of silver equal to fifty per cent. of the NH_3 present, and that seven per cent. ammonia dissolves about twenty grains per ounce, or equal to two-thirds of the NH_3 present. I may note, as a curious circumstance, that, although alkaline chlorides are solvents of AgCl , yet when we add salt, or sal-ammoniac, to a solution of ammonia nearly saturated with AgCl , the latter is copiously thrown down.

Advantages.—The advantages that may be claimed for the ammonia over the hyposulphite method of fixing prints are:—(1), Shortness of the time consumed between the toning bath and the finishing of the print (I here show a specimen which from the time of removing it from the toning bath until laying it down on the mount occupied less than eight minutes); (2), Freedom of the print from any sulphur compounds, and consequent promise of permanency; (3), Great saving of water required for the washings; (4), Preservation of the fainter shadings, which become bleached to a great extent under treatment with the hyposulphite; (5), The cost may be less, if the ammonia and dissolved chloride of silver and other silver compounds be recovered by partial distillation and treatment with hydrochloric acid; (6), The paler shadings in the picture retain a warmer tint than in the hypo fixed prints. This, in many cases, will be thought by some an advantage, as in portraits and sunny landscapes.

Against the ammonia method of fixing it may be admitted:—(1), That a longer and more thorough treatment with the gold toning bath is advisable (Captain Abney, it appears, finds the same to be the case when sulphite of soda is the fixing agent); (2), That the pink or other tinted papers have the colour more or less destroyed; but if a white paper be used, any desirable tint can be given after fixing; (3), That greater care must be taken that the sensitive paper is not exposed to much adventitious light; any slight shade of colour it may so acquire is not bleached out by the ammonia, as in the case of the hyposulphite fixing. For the same reason, the whites given by weak negatives will not be rendered so pure.

And now I may offer some remarks on the mode of using the ammonia. First, as to the strength; almost any strength may be used. On card No. 29 is given a print on a pink-tinted paper; this, after being thoroughly gold toned, was put in two. The one half was fixed in ten per cent. ammonia, or the "solution of ammonia" of the British Pharmacopoeia, having a specific gravity of 0.959—a much better standard for photographers than any of the stronger solutions. The other half of the print was fixed in quarter per cent. solution, or fully forty times weaker, yet little difference can be seen in the results so far as the fixing is concerned, only the stronger solution has more thoroughly destroyed the pink stain that the paper originally had. Strip one, on card No. 19, shows an attempt to fix an untinted print by means of a solution so weak as one-sixteenth of a per cent. It is really fixed, so far as the chloride of silver is concerned, but a little of some organic compound of silver has been left, and the sunshine has changed this to a buff or deep cream colour.

As to the Time Required.—When only one bath is used, this seems to vary just inversely as the strength of the solution, and the downward limit seems to be five minutes for a two per cent. bath, ten minutes for one per cent., and so on, or time = ten minutes divided by the number expressing the percentage strength. This, when only one print, is put into a considerable quantity of liquid, and frequently agitated; but a longer time is necessary to secure freedom from cream tint of the whites, and can do no harm. However, I prefer using several baths, and this really shortens the time required, at least when we begin with a strong bath and finish with a weak one.

When the silver and much of the ammonia are to be recovered, it may be a good plan to use two pairs of baths, the first and second baths being the stronger, say one or two per cent., and the third and fourth baths filled with weak solution, say of half or quarter per cent. The first bath should, after treating a few prints, be put aside for distillation, the second taking its place while a fresh second is supplied. When the third bath is judged to become impure, the liquid is to be thrown away, and the fourth put in its place and a fresh fourth provided. The accumulated liquid from the first baths may be distilled into cold water, producing a weak solution for the second pair of baths, and when most of the ammonia has been distilled off, hydrochloric acid is to be added to the remaining liquid. To throw down the silver or otherwise, three or four baths of the same strength may be used, all being marched upwards to the position of the first, and the whole eventually subjected to the still in a way that will produce a solution of the proper strength. On this plan very little waste will occur. When not pressed for time, and the contents of all the baths are to be thrown away, I would recommend using a one per cent solution for the first bath, and not less than five minutes immersion, this to be followed by baths of quarter per cent. solution.

As to the Final Washing.—If the last bath be weak and not very impure, there seems to be no necessity for after washing at all. Nevertheless, I prefer giving the prints a final wash in water, and in the case of using pink-tinted paper it may be noted that a wash with weak acetic acid revives to some extent the colour. But it will be best to use white paper.

As to the Cost.—Since the price of ten per cent. solution of ammonia will be from 2d. to 3d. per pint, that of one per cent. may be stated at one farthing per pint.

Before concluding, I may mention that some of the ready-sensitised papers are not very suitable for the ammonia treatment, as they become pimply or tacky, so that blotting-paper cannot well be used to dry the prints. Other papers are quite free from this objectionable feature. Should the revival of ammonia as a fixing agent meet with favour, much better results than I have shown will no doubt soon be produced. I especially look for improvement to spring from modifications of the toning bath.

ROBERT H. BOW, C.E., F.R.S.E.

WHERE TO GO WITH THE CAMERA.

BRIGHTON AND ITS NEIGHBOURHOOD.

It appears to me a curious fact that so few of our London brethren in the art really know anything of the vicinity of Brighton. If one hints at taking a holiday there we are instantly met with the query, "What is the use of going? There are no negatives to be got at Brighton." It is to these sceptics I should like to say a few words, and also do my best to give some hints for the benefit of those photographers who may by choice or chance visit our principal south coast watering-place.

In Brighton itself I must admit that the photographer who goes in for landscape views, old cottages, and rural bits generally, will certainly find a difficulty in obtaining subjects, as he will also do in most of our large towns. To the gentleman, however, who works with the detective camera, and whose chief aim is to secure studies of human nature, the beach and parade, especially during the excursion season, will afford him plenty of occupation. Some fine views of heavy seas are also to be had when there is a high tide with a strong south-westerly wind blowing.

Landscape views, as I have already pointed out, are not to be obtained in Brighton, but there are many in the vicinity if you know where to look for them, and a short railway journey will put you in the midst of some of the loveliest scenery in Sussex. To take a most popular place with artists, namely, Lindfield, the best way to get there is by train to Haywards Heath Station, where you are about a mile from the village. It is not a very interesting road, however, photographically, and, hence, a good plan is to travel by the omnibus, which meets most of the trains and which will put you down close to the church. In this locality you will find plenty of material for views, and a trip across the fields by an old ruined manor house at East Maskells, to Horstead Keynes, will repay you, and your stock of unused plates will rapidly diminish.

Excursions to the west of Brighton may also be made with advantage into the neighbourhoods of Bramber, Steyning, and Henfield, where numerous little bits—old thatched cottages, ivy-covered churches, water, &c.—may be found. To turn again eastwards into Glynde and its neighbourhood, on the line to Newhaven, will bring you across some rural and primitive scenes, while several quaint old cottages are also to be met with. To those who like long walks I should recommend a very invigorating one, which may be taken over the Downs, through the villages of Ovingdean, Rottingdean, Telscumb, Sonthese, and Piddinghoe, to Newhaven, where they can catch a return train to Brighton. I would strongly advise them, however, unless they are members of the Blue Ribbon Army, to take a supply of their favourite beverage with them, as in two of the villages above mentioned there is no accommodation whatever for the thirsty traveller. At one of them I had to call at four cottages before I could obtain even a glass of water. Another walk from Brighton is along the coast to Shoreham, taking the south side of the Basin running from Portslade to Southwick, where views of shipping, &c., may be obtained. The first part of the journey, however, is uninteresting, and it is well to get a lift either by omnibus or tram to Aldrington, where you can avail yourself of the ferry, and pass over to the south side of the harbour and proceed with your walk.

To enter into any detail as to the actual surroundings of the places I have mentioned would take too long a time, and therefore I have confined myself to pointing out some of the spots where views may be had with very little trouble. Many of them would repay a two or three days' visit, but putting up in a village when the elements may be against your working is not very enjoyable, and therefore I prefer to take as my centre a place with a little life in it, making daily excursions when the weather permits; and it is to those who hold similar views that I venture to suggest that they may go further and fare worse, photographically, than they will do in the neighbourhood of dear old, but much maligned, Brighton.

H. M. HASTINGS.

NATURE AND IMITATION IN ART.

On the occasion of prizes being distributed at the Croydon School of Art, Mr. Val Prinsep addressed the students. In the course of his remarks he said: "I would impress upon your mind the fact that all arts are really alike. They are to give pleasure to the world, and the artist has to impress what he feels in his heart, whether it be that he impresses that feeling and impresses that art in the language of literature or of painting, of music or of sculpture, or any of the other arts. We artists, with our usual presumption, have seized upon the name of artists, but we

are no more artists than the poet, the sculptor, or the musician. You here, in this School of Art, are beginning the language of the art of painting. You are doing good and excellent work of your kind, as good work as many other schools I have seen in Manchester and the big places I have visited; but though there is an enormous quantity of laborious and artistic work done in these schools, although you have shown considerable manipulative skill, let me point out to you that you are at the very beginning of art, that you are learning the A B C of the profession. You all know—most of us know to our cost—that when a person begins to learn an instrument, he has to spend much time in playing scales and exercises and other wearisome matters, and after having obtained certain facilities with his fingers, his friends may also, sometimes, know that he is unable to interpret any of the great works of the past masters, much less to compose himself. He becomes a mere playing machine, a kind of mechanical box, which may excite wonder, but cannot give any joy to the world. Now the aim and object of all arts is to give joy in this world, which would otherwise be dull indeed, and such a man's labours will indeed be thrown away if he can only show us manipulative skill without any art or thought. I do beg and pray of you to consider what it would be if you only became mere drawing mechanical machines. Now you will ask me how you can avoid doing so. In the first place I would beg of you to study drawing, for drawing is the grammar of the art. You must learn to draw, not only correctly, but with elegance, and to be able to express your feelings and thoughts in a manner that other people can appreciate, and which will give them joy. Now there are a great many books written nowadays which when a person reads he finds the style is bad, the sentences long and wearisome. The author has not found out the proper method of expressing himself. We, therefore, take that book and put it back on the shelf, or send it back to the circulating library, and say we will have no more of it. However great that author's thoughts may be, if he cannot express them so as to give us pleasure, of what use are they to us. But recollect this, that a picture, or a work of art, is always *en evidence* before us. It cannot be put on the shelf at all, and if it is to be appreciated and looked up to and be good in itself, it must have written on its face something that will give us pleasure on first sight and something that will repay us for looking at it again. For if you have it in a room you get to love it in all its parts, and if it is bad it is very bad indeed, not only for the picture, but for those that look at it. Now there are some amongst my own fraternity, and men of eminence, too, who think that the art training of the schools is not necessary. There are several instances of some of our very best artists who have not had that art training at all. I think this opinion is wrong. If they had an art training in their earlier years, if they had spent two or three years of their life in learning the elements of their profession, they would have begun earlier to do those masterpieces which we so much admire in their later time. As it is, you will find they were floundering about and learning their profession when they ought to have been masters of it before they began. I do not think myself that knowledge stamps out genius, or that professional skill necessarily does away with all invention and originality. There are some critics, too, who tell us artists that we are too fond of dwelling on the mechanical or technical parts of our profession, and that we therefore are not good judges of works of art. There again I naturally think they are wrong. A beautiful picture appeals to the artist, not only as it does to one who is not used to the art, but it says something to him a great deal beyond that. Always view with suspicion your own work as though it were the work of an enemy, and try and pick out the faults. Do not imitate, for those who imitate must always be behind. You will find in the course of time, when you gain experience, that there are many men who have attained considerable reputation and success, whose works are dexterous in the extreme, but whose works are really echoes of what has gone before. It is easy enough to account for their success. We all know that it is much simpler to understand a three volume novel than a great poem. One requires an effort, the other is nothing more than amusing, and has generally no backbone whatever. And it is so with art. Critics will always praise those things which are not difficult to understand, and it will be a long while before the original man can persuade them that what he does is really good. But the original man has no need to be additionally proud when he finds he has attained success. I have been impressing upon you the necessity of being original. There are dangers again that beset even the original man, for it may be that he will drift into eccentricity. Now that is a great danger to my mind, for eccentricity is not genius, though it is very often taken for it. The great geniuses are never eccentric. The other danger is the danger of vulgarity. It arises from pretentiousness. It comes from a desire to display yourself in your work, so that people looking at it are apt to exclaim, 'What a clever fellow that is!' Now a man who shows himself in his works to that extent is not a great artist, and never will be a great artist. The great artist shows a great mastery, no doubt, but there is always a feeling of reserve of force in everything he does. To do a work you must do it from yourself. You must not think of yourself when you are doing your work, but of the work you are doing. Earnestly and laboriously you may work at it, but do not let self intrude to any extent. Now there are characteristics in every age that mark at once the art of that age. In the last age we know there was a kind of pseudo-plasticism, when men wrote their epitaphs in Latin, like Dr. Johnson wrote Goldsmith's, and refused to allow English to enter into the precincts of Westminster Abbey,

and when that great painter, Sir Joshua Reynolds, was apt to clothe his ladies in dresses which he chose to think classical, but were nothing of the kind. That age has passed by, and the aim and object of everybody now is to be natural, nature being the great inspirer of the modern arts at the end of this century. Now nature, no doubt, is full of poetry. Nature is never vulgar, and nature is all around us. If you look at that great cartoon of Raphael's of the *Beautiful Gate*, you will see there a low, horrid, dirty, and depraved man. But he is not vulgar, for Raphael has stamped him with his genius, and placing him there as a contrast to his other beautiful figures, that low and dirty figure becomes the centre of the picture. That is the way to treat nature. You have it all around you. You have the sky above, with its clouds and its thunder, and its rain and sunshine, and its beautiful moonlight. You have the fields, greener than the greenest emerald, the trees with their infinite variety of tone and formation, and the hedges, full of an amount of design which would supply twenty such schools as this. You will find forms repeated in the branches of the brambles and thorns where every leaf varies from its neighbour just so much as to make up a true harmony among them. We have the little flowers twinkling in the grass in all varieties of colour and form. All these you ought to study and form your style upon. The gift of imitation is not art, otherwise the Chinese artist, who imitates even to deception, would be a greater artist than Raphael himself. But in all these works of nature you must put yourself and your own individuality out of sight as you do in your drawings and everything else you put your hand to. You must render it and not imitate it, and when you have done that, and when you have studied in the way I have described, you may then attain to that proficiency that you may understand the great language of the masters of the past, and a great picture of Titian or Raphael will give you pleasure."

THE STEREOSCOPIC PICTURE.

Why has this, the most satisfactory of the pictures made by photography, been so long neglected, if not altogether forgotten? There was a time when it was about the only style of photograph sold in the shops. There was a day when such houses as Appleton & Co. thought enough of it to operate an establishment where such pictures were made, and there was sale enough for such a house to have a department exclusively devoted to their handling. What reason can any one give for their having fallen out of the fashion? To me there is about the same reason that exists for the strange and senseless change in fashions. One year it is a hat with a narrow, flat brim, the next one with a broad brim, and a roll in it at that. It must have been some such good course of reasoning as this that obliterated the stereoscopic picture, and we who made them were all fools enough to follow the fashion in this, as in hats and pantaloons. There was a time when the amateur made this picture, no matter what other size he made; this was the only picture that was recognised by the exchange clubs. I do not wonder that those now in our ranks, who have joined since the advent of the dry plate, do not make this charming picture. Of it they know not. I do not wonder why it is that we, the old hands at the bellows, should have so thoroughly forgotten our early love. For one, I'm back. Now that I am, I wonder more than before why I have neglected this picture so long. The older hands remember well how many pretty bits we had to pass by because we could not give the needed time for exposure, fearing that our wet plate would crystallise. No such trouble now. We know, as well, how many lovely bits we had to pass because it was too long a run from our tent, or was but a single view; this does not trouble us now, for we can make our pictures as we move along. To those who know nothing of this style of photograph, I beg simply to say that it is suited to all those dark secluded beauty spots that are useless in the single picture; it gives the most minute detail and the best idea of distance, and is in many ways the most interesting picture the amateur can make. Who of the old ones seconds my motion to revive them? Who will join me? I have a presentiment that I will not stand alone in the coming photographic season.

—*Photographic Times*.

CHARLES WAGER HULL.

WHERE I WENT WITH THE CAMERA.

No. II.—ROTTERDAM.

I HAD been in Rotterdam once, some years before, but on that occasion I was not impressed by its beauty. One reason might have been, that when going out to peregrinate over the place I got lost, and had considerable difficulty in finding my way back to the hotel, not being able to speak the language making the matter ten times worse. So that from time to time when I have heard that Rotterdam was an interesting and beautiful place, grave doubts have lingered in my mind regarding the grounds on which it could be so described. However, these doubts floated away like a mist as I drove from the quay to the hotel. Beautiful trees, handsome villas, and quaint, interesting streets—picture after picture crowded on my view as we sped along, leaving me surprised and pleased, and the nightmare Rotterdam of my previous visit was gone for ever. I put up at the Pays-Bas Hotel, a very comfortable house, and as the advertisements say, "attendance good, charges moderate." I arrived on a

Sunday morning. After breakfast, I started to try one of the light cigars of the country, as I sat down at the coffee-room window to have a look at the living and moving diorama passing and repassing in the street. For Sunday is a holiday, and the street is thronged with more pleasure-seekers than churchgoers, and the incessant hum and noise keeping time and tune to the constant "clang o' the wooden shoon," the clank, clank, of which played upon the ear continually.

The first thing that struck my fancy as being most grotesque and peculiar was the head-gear of the women, and as I looked at them one after another as they moved to and fro I had a quiet laugh all to myself, they looked so funny. Mostly all of them had muslin caps, beautiful in their cleanliness and purity of white—in some cases they had broad band strings thrown over the shoulders and hanging down the back, whilst immediately above each ear gold wired screws projected in front beginning about two and a half inches diameter at the start, and twisting out to a point at each side of the head; others wore fancy plates of polished metal and ornaments on the brow, fastened by metal bands round the head; and for variety, old ladies especially, had an ordinary poke bonnet surmounting all this finery. To the ignorant foreigner it was as good as a play.

Asking the method of their madness, I was informed that each of the varied styles of head-dress denoted the district or country to which the wearer belonged, so that they were really jewelled sign indicators of locality. When inquiring for information regarding the habits of the people, I noted many quaint and peculiar customs, for instance, I was told that in some localities, when a baby is born, a pincushion is tied to the handle of the door of the house where the little stranger has arrived, this by way of announcing the fact, and the colour of the pincushion designates whether it is a boy or a girl. Another custom, when any one is ill in a house, a small placard is fixed to the handle of the door, stating the condition of the patient, thus saving noise and ringing of the bell to inquire. Both of these habits seemed to me strange, but sensible.

I went to visit the Great Church, or Groote Kerk as it is called. Visitors are directed to this church as one of the sights of Rotterdam; but it seemed to me that, outside and inside, size was the only quality that it possessed, for a church more barren of architectural pretensions I never saw. Service going on, I had to wait half an hour before gaining admission. The first strange thing that met the visitor's gaze on entering was, all the men sitting with their hats on during service. Draughts might have had something to do with the origin of this fashion—for the church was cold and draughty—but to the stranger from other shores there seemed a lack of reverence in wearing this head-gear, considering the place and the service. Of course, they will think nothing of it: it's the custom of the country. The walls and side recesses of the church were filled with statues, monuments, and tablets, sacred to the memory of many heroes who had lived and died for their country's good. These names were manifold, and to me unpronounceable.

Next morning I started to photograph. To prevent the recurrence of losing myself I engaged a guide—David Abas by name, and a very worthy fellow. Should you wish a guide at any time when in Rotterdam, you will find him at the Pays-Bas Hotel, and I have no doubt but that he would be of great service to you. Being thoroughly well acquainted with the town, I got him to take me all over the place. The views that pleased and suited me I photographed, and those that were unlikely I left and went on.

From the crowds that gathered when I was putting up the camera previous to exposure—which was never more than three minutes at any time—one could at once see that photography out-of-doors was a rare thing in these parts, unless they did it professionally very early in the morning. My guide told me that he had never at any time seen a photographer in the street, and I can tell you it took him all his time to keep the crowd back. Oh, yes, we have crowds at home, but nothing like this. I did get the better of them sometimes. A good position could be had, it might be at the corner of a canal bridge where they could not possibly get in front, then the matter was easy; but the crowds gathered so quickly that the way across the bridge would be blocked in three or four minutes. A Punch's Opera could not have created a greater stir. It always seems to me that the uninitiated have got it into their heads that we really are some kind of show fraternity.

I was charmed with Rotterdam, and more especially the thickly populated parts of it, where the canals and water-ways hold their own. It was all so new and strange. The quaint old buildings, towering up four or five storeys high, all smudged, and bedaubed, and painted, by storm and sunshine and old Father Time; old houses with wood patch-work and projections, leaning over the canals as if awary of standing straight, or as if age was making them stoop a little, rendering them toppy and unsafe to the view; while below, the long, flat-bottomed boats moving leisurely up and down, or lying sleepily by the water side—these boats, in many cases, being the floating homes of the possessors. Many of them are painted green, and red, and yellow, broad patches of colour standing out from the dull muddy water, brightening the scene; whilst the foot passengers, the horses, and dogs, and carts, coming and going along the narrow sideways, all combining to form a striking picture. At such a time, and in such a scene, comes the oft-repeated exclamation, "Oh, that I could photograph the natural colours."

In the vicinity of the Groote Kerk are a lot of very narrow, intersecting streets, quite filled with old, curious, artistic studies, a wealth of work for

the painter, places where the aged buildings lean forward so much towards the top that the houses on one side seem to be having a chat with their neighbours over the way. All these houses are built on piles, which gives them this toppling tendency. The guide told me that they were perfectly safe, in fact, had stood in this precarious condition for many, many years. That was right enough I thought, but I for one would not like to live in them.

The more fashionable parts of the city are quite as interesting in their way, but more modern. The merchant princes' houses down by the parks are, in many cases, palatial in their magnificence. The park has within itself plenty of subjects and good pictures for many days' work. The Zoological Gardens is also a feature of considerable interest. Two or three weeks could be spent in and around Rotterdam without subjects palling upon the tourist photographer, and he would still leave plenty for the next comer.

Before leaving Rotterdam I thought that I would like to purchase some pyrogallie acid and ammonia and a couple of trays, so that when I had a little leisure I might develop a plate or two, as I had never before worked the lens I was then using, and I wanted to see how the negatives were going to turn out. So I got the guide to take me to one or two photographers' places, but they were using ferrous oxalate, and they had not trays to suit, and preferring the pyro and ammonia developer I asked the guide to take me to some photographic stores. For three hours I wandered round and round to opticians, apothecaries, and electrical apparatus warehouses, and not a living soul seemed to keep or know about photographic apparatus or photographic chemicals; they were all bought in Amsterdam was the usual refrain. I was shown all kinds of substances for pyrogallie acid, not the least strange amongst these being powdered French chalk. At last I managed to get the chemicals, and resolved to use kitchen plates for trays when the opportunity arrived. Moral, always carry a small supply of necessary things with you, they don't take up much room and are sure to come in handy.

MARK OUTE.

AUTOBIOGRAPHY OF C. E. MULCYON.

It may seem a very strange thing to some people that a humble individual like myself should venture before a reading public with an account of myself and a history, even though it be a short one, of the adventures that have befallen myself and some other members of my family. But biography and even autobiography have sometimes proved so beneficial to the public that I am led by my interest in the general welfare of my many relations to lay aside for the time being my usual modesty, and to enter into certain private details concerning my life that otherwise my retiring disposition would have constrained me to hold as secrets in my own bosom, or at least to withhold from the general ken as unimportant and trivial.

I am one of a family of four, being the third of that number born to my parents. My father was universally acknowledged to be a man of sterling worth, holding an important place in the Mint, and at certain times he dabbled in medicine. He was called Mr. Silver Nitrate, but his more intimate friends were in the habit of calling him AgNo₃. My father came of a good stock, and he was so pure of morals that he was sometimes jestingly called "Re-crystallised." Though his respectability was unimpeachable he could at times be very caustic, yet he never, if properly treated, displayed any acidity of temper. My mother, Mistress Bromide Potassium, was a lady of an amiable temperament approaching at times to drowsiness, yet in spite of her less enterprising nature her lineaments appear in all our family in excess of the more marked features of our father. My mother had a very small affection for alcoholic liquors, which was greatly to her credit; my father, though never addicted to intemperance, would melt considerably under the influence of a glass of hot spirits. A maiden aunt lived with the family and undoubtedly gave a tint to all of us, though she was of very small size in comparison with the rest of the family. She was a sister of my mother, and went by the name of Miss Io. Potassium, or more familiarly "K I."

Our nurse was a very important person in our little family. She bore us all in her warm soft arms from our very birth. We always called her "Jelly," which was our familiar abbreviation of Gelatine. In her earlier years she was, as all have heard, slim and threadlike, but just before we were born she had got a severe drenching in a pool of water, and thereafter she had swelled very much and become quite dropsical. The slightest heat caused her to dissolve, but she was at such times all the more willing and able to carry us, and prevent over-hasty collisions between my father and mother. Of our ancestors before our father and mother I have but little record; the family Bible, however, informs me that my grandfather was an amateur photographer living in the South of Scotland, whose chief pleasure and occupation, so far as we are concerned, was noting the actions, and keeping carefully the records, of the various members of the family.

It is now time for me to give some history of my brothers, and I will begin with a short sketch of my eldest brother's character and history. There was very little difference in our ages, for my eldest brother was born on the 18th of March, 1887, while I, the third of the family, first saw the light on the 22nd day of the same month. We were very like each other in personal appearance while we were in our infancy, the only

difference being that I took more after my father than my eldest brother. Jocular chemists used to say my brother had ten per cent. of extra likeness to my mother, while I had only about eight per cent. In other respects until we went out into the world there was a very strong family likeness between us. My brother was intended, as I was, for the lantern profession, and his character was of so staid a nature, and his mind so very clear, that he soon distinguished himself in that line, though he might almost be called an indolent man. My eldest brother was brought up in a much cooler climate than I was, he never felt any heat greater than about 200° Fahr., and that only for a few minutes. He only got one thorough washing in his youth, and that was in a teapot into which my grandfather in a rage squeezed him through a horrid cylinder with silver wire gauze at one end. But he was always a very clean boy, so that the two hours' washing he got must have been a very effectual one. Grandfather, enraged still more at the backwardness and slowness of my poor brother, again put him in a very hot bath, quite boiling this time, and left him there for several minutes. But my brother must have been destined always to be slow, for he did not improve in this matter, but still retained his admirable lucidity of expression, and grandfather at last came to see his good points and kept him in a very honourable place, until my brother died a peaceful and natural death, having fulfilled his mission on this earth with credit to himself and satisfaction to all his kindred. This brother was called Andrew, or more shortly "A.," after his grandfather, as is the usual custom in the land of our birth.

The next brother, "B.," or Bob, was of larger build than his elder brother, but in education and appearance during their youth no difference could be discerned between the two. B. was just twice the bulk of A. It is true that Nurse Jelly through an accident got too near a fire with my poor mother Bromide in her arms, and my mother being at that time in an interesting state and very near giving birth to my brother, this mishap may have affected my brother in his after life. Anyhow, nurse and mother got boiled for a minute before grandfather reached the spot to save them. And, further, grandfather, thinking to make B. a livelier boy than A., boiled father and mother and nurse all together for five minutes. B.'s life was altogether a sad and an unfortunate one, for he caught *scarlet fever*, which grandfather first discovered when B. was sent out into the world on his own account. Grandfather being a man of rather a hasty temper, poor B. was at once buried in an urn containing a poison deadly to us.

Before I enter in detail into my own history, I will say a few words of the only member of our family yet born younger than myself. This, my younger brother, was baptized Duncan, and he was from the first very like my brother A. The scarlet fever contracted by poor B. caused my grandfather to give my mother a dose of acid shortly before D.'s birth, and I must own that Duncan has been an honour to our family; though not very brilliant in his talents, he had, like A., a thoroughly clear way of expressing himself, and he still lives, held in high respect for his qualities of sterling though not startling worth.

In bulk and in character I was very like my poor brother Bob, and up to a certain point my history is very much parallel to Bob's. There was a little more of my father in me than in Bob, but no one could ever detect any marked difference between us until the great event of my life. It happened in this wise. Both Bob and I had been treated to a little spirits, in order that we might not remain too long wet and so catch a chill after a long bath we had had; in fact, we had both been broken up and washed in a running stream for over two hours. Whether it was that our mother had suffered from alkalinity, or whether our grandfather's "blend" was adulterated, I cannot say; but certain it is that I caught scarlet fever just as Bob did, and had an attack equally severe. Grandfather was very angry that I, too, should have caught this disease, and would have killed and buried me beside Bob had it not suddenly occurred to him that there was in London, a village in the south of England, a great and famous doctor, called Henderson. Whether it was that this Doctor Henderson had been so very often in a fever himself as to be inoculated and impervious to such exanthematous diseases my aged parent did not know, but he knew that this doctor was really a famous and an able physician and not a quack, nor a vendor of secret pills and ointments, and he resolved to send me for a course of treatment by this great *savant*. So to Doctor Henderson I went. His treatment was very rough, no doubt, but there was such an amount of exhilarating change and healthy exercise in it that I did not so much object to the cure as some might conceive. The Doctor took me into a little room, where I saw an instrument of torture far more awful to look upon than anything I ever saw in my grandfather's house, or even at a dentist's. He put me into a very nice shiny silver apartment and began to turn a wheel quickly. I thought certainly my last hour was now come, for I rushed round the little room at a fearful rate. Still, all the time I was rushing about I felt that the fever was leaving me, and when the doctor had ceased his exertions I felt very thin and worn out, but quite clear in the mind. The doctor had with great thoughtfulness sent for my old nurse, Jelly; into her arms he once more put me, and in this state I went back refreshed, vigorous, and cured, to my doting grandparent. He at once tested my strength of body and mind, and found me now so much improved, and so much more intelligent and quick, that he saw I should be thrown away, if indeed not too enterprising and hasty, for the lantern profession, and so he sent me out as a Landscape Photographer, a calling which I now follow to my own and my progenitor's satisfaction.

I can never sufficiently express my gratitude to Doctor Henderson, of London, for the wonderful cure he worked on me; and I can heartily recommend any of my friends or relations who have caught the awful disease, which so nearly destroyed me, to apply to the Doctor at once. Grandfather says he would at once, if he could command the means, buy from the Doctor his wonderful cure, but, failing this, he means to try to make for himself a "merry-go-round," which, if it will not cure scarlet fever or jaundice, will at least amuse the children with the smallest possible loss of fingers.

CHARLES E. MCLYTON.

Department for Inexperienced Photographers.

THE ENAMELLING OF PRINTS.

WHILE there is a charm in a fine photograph taken on plain paper having a matt surface, there is also a peculiar charm in one of precisely the reverse character, that is, one in which the surface is not only smooth, but glassy, the grain of the paper being obliterated. When a small oval portrait is "*glacé*" it is a matter of extreme difficulty to distinguish between it and a similar portrait which has been vitrified or burnt in upon an enamel plaque.

But not alone is enamelling applicable to portraiture; landscapes also have a wonderful degree of lustre imparted to them when subjected to the *glacé* process.

In enamelling prints the first requisite is a plate of glass. This must possess a flat and well-polished surface and be quite free from scratches or other imperfections. The necessity for this will be apparent when we say that the most minute defect on the surface of the glass will be afterwards visible, more or less plainly, on the print when finished. Plate-glass should be preferred to any other. The plate having been obtained it must next be made quite clean, a final polish being given with a wash leather. A number of plates ought to be prepared at a time, and after being cleaned each in succession is stored away in a grooved plate box.

It is difficult to lay down any rule for determining the size of the plates, but it will conduce to ease in working if the dimensions be such as to permit of from six to twelve small pictures being laid down at a time. For half-plate size, four pictures will be a suitable number to place on one plate, two prints of whole-plate size sufficing. But this is a matter for the individual convenience of the operator, who, if he chooses, may employ plates no larger than the pictures.

Next, take a small quantity of powdered French chalk and tie it up in a piece of muslin, so as to form a ball the size of a walnut or an egg. This is applied to every portion of the surface of the plate with a fair amount of friction, beginning at the centre, and taking particular care that no portion is omitted. Inattention to this will cause the picture to adhere to the glass at a subsequent stage instead of stripping clean from off it. Having dusted off the superfluous French chalk, coat the plate with plain collodion. Some of the finest enamels we have seen were made with collodion consisting of four grains of pyroxyline and four drops of castor oil dissolved in half an ounce each of methylated alcohol and ether. But almost any good plain collodion will serve the purpose, provided a little castor oil is added to impart toughness. The plates thus collodionised, after being allowed to stand for half an hour, receive a coating of gelatine which has been prepared by pouring upon it a quantity of cold water just sufficient to cover it.

After standing for a few hours to permit of the water being absorbed, the vessel containing the swollen gelatine is placed in a larger one containing hot water. This immediately effects the liquefaction of the gelatine, which is then filtered through muslin into any convenient bottle having a wide mouth. This bottle should previously be made warm by immersion in hot water, or otherwise, to prevent any fracture which might occur through filtering warm gelatine into a cold bottle.

The gelatine thus prepared is applied both to the collodionised plate and also to the print. In the former case, a little is poured on the centre and spread by guiding it over the surface by a slip of stiff paper or a glass rod, after which the plate is left in a horizontal position until the gelatine sets, when it is reared up on end and allowed to become dry. As the plates when thus treated keep well, enough may be prepared at a time to serve for a whole season.

When required for use, lay one of them face up on a flat table, and having some warm gelatine (from the same stock bottle) poured out into a dish, immerse in it the prints, and then lift them out one by one, and lay them, face down, upon the glass, arranging them side by side, so as to economise space. When they have all been placed down, raise the glass, and looking through it examine each print carefully to see if no air bubbles intervene. Wherever one is seen, press the paper with a squeegee or the point of the finger and run it out to the margin of the print. We fre-

quently secure the perfect adhesion of the print by passing a wet sponge over the back.

The glass plate with the adhering prints is next reared up in a current of air to dry, and the drying should be of a thorough nature. According to the state of the atmosphere the drying will take from twelve to twenty-four hours. We need scarcely say that by having recourse to a warm (not hot) current of dry air this time may be very greatly reduced.

When dry, strip the pictures from off the glass, and it will be found that they have a surface rivaling that of the glass to which they were attached: this surface consists of collodion, to which they are firmly secured by the intermediate layer of gelatine.

The presence of the castor oil in the collodion so toughens the film as to prevent it from easily getting scratched or otherwise damaged.

As we have described it the process may seem a little troublesome, but it is not so in reality, as those who give it a trial will speedily discover. It may be simplified in some measure by transferring the plate, after being collodionised, to a dish of water, and then, having previously sponged the surface of the print with gelatine, laying it down upon the wet collodionised surface, and allowing it to dry as before; but the resulting print is not so brilliant as when finished by the method we have described.

RECENT PATENTS.

PATENTS COMPLETED. IMPROVEMENTS IN CAMERAS.

No. 5450. WILLIAM MIDDLEMISS, Ailee-street, Bradford.—April 20, 1886.
The first part of my invention has relation to the camera front, and its object is to enable the front to be readily fixed in position and to be folded into the camera bottom.

The camera front, to which the bellows is attached, is made to slide between the sides of a forked frame as usual. To the sides of this forked frame are attached with set screws two brass struts, and the ends of these two brass struts are pivoted to the frame which travels in the camera bottom. At the bottom ends of the sides of this forked frame two pins are fixed, and these pins are made to go into two hollow places at the front end of the frame in the camera bottom. When the pins are placed in these hollow places two brass turnbuttons or catches are made to turn over them to prevent their lifting out; thus it will be seen the forked frame may be swung backward and forward and fixed in position by means of the two struts.

When it is required to fold up the front, the bottom end of the forked frame is released, slid on the camera bottom to the back end, and the combination of forked frame, struts, and camera front, laid down in camera bottom with its face downwards.

The second part of my invention relates to the camera back, and its object is to enable the camera back to be readily moved from one end of the camera bottom to the other.

The camera back is pivoted between two brass plates; to these two brass plates are also pivoted the bottom ends of the two struts which keep the camera back in position. These two brass plates are made to slide against the sides of the camera bottom from one end to the other. To the sides of the camera bottom are fixed two brass plates having slots made down the centre of them, and behind these plates are made to slide two bolts or set screws.

By means of these two bolts the brass plates to which camera body and struts are pivoted may be fixed at any part of the camera bottom.

A NEW OR IMPROVED PROCESS FOR REPRODUCING PHOTOGRAPHS IN COPPER-PLATE, LITHOGRAPHIC, OR PRINTING PRESSES.

No. 5595. LORENTZ ALBERT GROTH, K.G.V., 30, Finsbury-pavement, London, E.C.—April 22, 1886.

THE object of this invention is to reproduce photographs in copperplate, lithographic, or printing presses in a better and cheaper manner than heretofore by means of the common photographic press.

In order to obtain such a result the photographs to be reproduced must be provided with a surface in relief, as with the ordinary smooth surface such reproduction is impossible.

For this purpose a specially prepared gypsum mass, as also a specially prepared pigment paper, is required, from the latter of which a negative is taken, and which can then be used as a medium for producing an irregular surface of crooked lines and figures from the half tones.

The gypsum mass is composed of one to six per cent. chalk and fifty per cent. water to each one hundred parts gypsum, the latter, together with the chalk, being finely powdered and well worked with the water to obtain an homogeneous mass, which is then pressed into plates of suitable size, having a polished surface when dry.

The pigment paper is prepared as follows:—

Common black pigment paper is placed in a bath composed of four per cent. bichromate of potash to one hundred per cent. water for from one to five minutes, as required, and then dried in a temperature of 60° to 70° Celsius. The paper is then exposed to the daylight for from ten minutes to two hours, according to the strength of the light, and then placed in cold water for about an hour, and then in another bath composed of about six per cent. pyrogallie acid to one hundred per cent. alcohol for about ten minutes, when it is placed in a frame or on a plate and dried.

As soon as completely dry it is covered with powdered oxide of zinc, or oxide of bismuth, which is rubbed in with the palm of the hand, thus pressing it into the deep parts, and leaving the upper parts or lines of the figures free the surplus powder being removed.

The pigment paper thus prepared is placed in front of the camera, and a negative produced in the usual way.

This negative is removed from the glass and placed between the negative of the photograph to be reproduced and a pigment paper which has been prepared with a strong solution of gelatine, containing only a small quantity of pigment, and then copied as usual, thereby producing a positive on the pigment paper with the same irregular surface as that on the negative which is necessary to print from.

The printing block is prepared as follows:—

The gypsum plate is placed under water, and upon it the positive also under water, and then the plate with the positive is removed from the water, and the positive pressed against the plate by an indiarubber roller or squeezer to remove any air that may be between, the positive closely adhering to the plate. It is then pressed slightly in a press, and then placed in a bath composed of water and ten per cent. sulpho-cyanure ammonium or rhodon ammonium, which will dissolve those parts which are not or only partially developed.

When removed from this bath and washed in cold water, it is placed in a bath composed of five per cent. chrome alum in water for about five minutes, then removed and washed and immersed in a bath of concentrated alcohol and dried, and then impressed into a plastic mass composed of bone dust, albumen, blood, and silicate of soda, the proportions depending on the hardness required. Any other plastic substance may be used, such as celluloid, cyanoid, &c., by means of an hydraulic press or other suitable means, steam being introduced during the operation, as is usual in filter presses. When cold it is removed from the press.

The claim is:—A new method of reproducing photographs, consisting in the production of a peculiar negative in connection with a black pigment paper, which, after having been exposed to the light, is covered and rubbed in with oxide of zinc, or oxide of bismuth, to transform the half tones into irregular surfaces suitable for reproduction in any printing press; copying the said negative on pigment paper and transferring it to a specially prepared gypsum plate, which is then impressed into a plastic mass composed of bone dust, albumen, blood, and silicate of soda, or any other suitable plastic substance, and then forms the definite printing block, substantially as hereinbefore described.

PHOTOGRAPHIC CAMERA LENS SHUTTER.

No. 12,250. JAMES SWIFT, 51, Tottenham Court-road, London, W.—September 27, 1886.

AN improved instantaneous and time photographic camera lens shutter, which consists of two parallel slides working in same grooves and plane, made of any suitable material, the edges of which meet and slightly overlap each other in the centre of the aperture of the camera lens with which it is used. When in action the lower segment is forced downwards by a spring, while the upper part of the shutter is thrown in the opposite direction also by a spring, thus leaving the entire aperture of the lens exposed to the action of the light. The same portion of the shutter when forced up by the spring returns by recoil and closes the aperture. The return of this part closing the aperture can be made, at the will of the operator, from a fraction of a second to any number of minutes. I further claim in my invention the method of detaining the upper segment of the shutter for time exposure before allowing it to close over the aperture of the lens; this is effected by a loose hinged piece, which is made to shift into position when required, so that the upper portion of the automatic piston arrangement for discharging the shutter when put into action comes in contact with the aforesaid hinged piece, which forces a tension spring on the upper segment of the shutter and holds it in position until the pneumatic pump is relieved by the pressure of the hand, when the piston rod descends and releases the tension on the segment of the shutter, thus allowing it to fall over the aperture of the lens. I further claim that the two segments of the shutter can when discharged be made to travel over the aperture of the lens with only a partial opening between them. This contrivance is necessary for very rapid exposures in bright atmosphere.

What I claim is, the application of the sliding shutters meeting over the aperture of the lens, only one returning to shut off the light after exposure has been made, and also the upper segment of the shutter can be retained in position for any length of time, at the will of the operator, after opening the shutter before it is allowed to descend to shut off light. I further claim the mechanical arrangement of holding the upper segment of the shutter until required to drop.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, April 7, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. Alexander Cowan presided.

Mr. A. L. HENDERSON exhibited two photographs taken by him by artificial light at the Royal Aquarium, Westminster, representing the orchestra and stage while a performance was going on; the camera was planted upon the opposite gallery, and the time of exposure was one second with a $\frac{1}{2}$ double lens. The electric light, the limelight, and gas, took part in the illumination at that particular part of the performance. He did not know why the orchestra came out in good focus in both pictures and the actors on the stage in a slightly hazy condition; it was not the fault of the focussing, nor did anything of the kind appear with the same lens in daylight; would the artificial light make a difference in the working of the lens?

Mr. A. HADDON thought the effect to be due to unequal refraction by the warm currents of air rising from the footlights between the orchestra and the stage.

Mr. HENDERSON responded that that seemed to be the true explanation.

Mr. F. W. COX exhibited an albumenised print which had been "knocking about" for a quarter of a century, yet was nearly as good as when first printed; it had been produced by Mr. W. England.

A question in the box asked whether a patent could be sustained for stripping films.

Mr. HENDERSON asked what was the difference between Eastman's stripping films and the "diaphanous paper" once in the market.

Mr. A. MACKIE responded that the stripping film of diaphanous paper was upon albumen and not upon gelatine.

Mr. HENRICH TRINKS remarked that in many mechanical processes gelatine had long been used to strip from paper.

The CHAIRMAN thought that the question could not be answered before knowing the claims in the patent.

Mr. MACKIE asked what was the maximum of chrome alum which could be added to gelatine.

The CHAIRMAN replied that he did not think that more than half a grain of chrome alum could be added to each twenty grains of gelatine if the latter had to be remelted, but much would depend upon the kind of gelatine. Before it had set, and if remelting were not intended, it would bear a large proportion of chrome alum.

Mr. HADDON said that if the gelatine were not intended for photographic purposes he thought that the presence of some acetic acid would enable more chrome alum to be added; in adding it the gelatine should be dissolved in the minimum of water and the chrome alum in the maximum.

Mr. HENDERSON said that once Mr. W. Cobb had called his attention to the fact that he could produce phosphorescence in his emulsion jar by rubbing it with a glass rod when there was no emulsion in it; the light might have been due to electricity. The friction of a plate against a vulcanite tray will sometimes cause light and photographic fog.

Mr. TRINKS had once had some exposed stripping films which prematurely began to strip themselves automatically, and wherever they did so they gave off phosphorescent light and fogged.

Mr. HADDON said that if a warm, dry film of gelatine were rapidly stripped from glass it was so electrical that it would stick against a wall.

Mr. MACKIE stated that Eder had suggested that the light sometimes seen in photographic operations might occasionally be of the nature of that emitted by arsenic when crystallising from its solution in hydrochloric acid.

A question in the box asked if any good practical method were known of making oxygen and hydrogen near the optical lantern and using them as fast as they were produced.

Various speakers suggested Chadwick's generator, also a plan said to have been tried in America.

The CHAIRMAN remarked that no one present seemed to have had experience in the matter.

Mr. TRINKS and Mr. HENDERSON made some remarks to the effect that the results given by a sensitometer with a luminous tablet formed but an imperfect and sometimes misleading guide to the speed of the same plates in the camera, the kind of light not being the same in both cases.

Another question asked if the range of gradation of albumenised paper could be varied at will by its mode of preparation.

Mr. HENDERSON said that if paper were to be partially fumed with ammonia in those parts where the densest portions of the negative had to be printed it would be more sensitive there.

Mr. MACKIE remarked that toning altered the gradation; it attacked the half tones more than the shadows.

Mr. J. J. BRIGGS said that the longer paper had been sensitised the less range of tone it had.

Mr. S. G. B. WOLLASTON was elected a member of the Association, and the proceedings closed.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The Committee of this Association met on Wednesday, the 6th instant.

The minutes of the previous meeting having been confirmed, Messrs. W. Budd, J. Blakey, — Cobb, A. C. Clement, L. England, T. E. Freshwater, H. J. Gifford, F. Hamblay, W. H. Hyslop, F. Ince, L. Kidd, J. D. O'Connor, C. Pearce, A. C. Rees, J. A. Randall, H. Scott, W. Strickland, C. H. Trinks, — Tompsett, S. G. B. Wollaston, C. A. Watkins, and Miss M. Coulson, were elected members of the Association.

The correspondence having been dealt with, Mr. BEDFORD made a suggestion that honorary members should have the right of nominating deserving cases of non-members for the consideration of the Association. After some discussion on the subject, it was decided that a special Committee meeting be held to fully discuss the matter.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held on Tuesday, the 5th instant, at Myddelton Hall, Islington, N., Mr. J. Traill Taylor, President, in the chair, arrangements were made for an outing on Easter Monday at Maidenhead.

Messrs. T. Bird, A. Liddle, and A. Wybrant, were proposed for membership.

A question was asked as to the composition of sulpho-pyrogallol.

Mr. F. W. COX replied that Mr. Berkeley's original formula was one ounce of pyrogallol acid, four ounces of sulphite of soda, nine ounces of water, acidified with a little citric acid.

Mr. A. MACKIE believed that the Platinotype Company's solution was acidified with sulphurous acid. He found in practice that two ounces of sulphite of soda to one ounce of pyrogallol acid was sufficient.

Mr. E. CLIFFORD had been experimenting with meta-bisulphite of potash in place of the sulphite of soda. He found that it preserved the developer from oxidation admirably, but that a considerably larger quantity of the alkali was required, as it contained free acid.

Mr. L. Medland showed some photographs of snow scenes, also some instantaneous views of the boat race; he also exhibited a light and portable tripod stand made by Horne & Thornthwaite.

A question was asked whether any member had had experience with the mercurial intensifier, using sulphite of soda solution instead of ammonia.

It was the experience of several members that sulphite of soda did not give as much increase of density as ammonia.

The PRESIDENT then gave a concise and interesting account of the latest improvements in stripping films.

It was announced that the next meeting would be held on Tuesday, the 19th instant, and would be a lantern meeting. Visitors are invited.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held in the Masonic Hall on Tuesday, the 5th instant, — Mr. W. B. Hatfield, Vice-President, in the chair.

An excursion to York was fixed for Wednesday, the 4th proximo.

Messrs. F. Crawshaw, J. Hunt, B. J. Taylor, E. Beck, and F. Motterslaw, were elected members.

The question-box was opened and contained two questions. "What is the best way to keep plates after exposure?" elicited a discussion in which the plan of packing them tightly in a mass film to film and glass to glass without anything between seemed to find the most favour. The other question was, "What is the best developer for a beginner, and what the best way of proceeding?" Nothing definite arose out of this beyond advice that a beginner should adhere to the directions given, modifying them only as to the amount of water (diluting for over exposure), and after gaining experience he could make further alterations.

The Secretary was asked if he had received a circular respecting the Glasgow Convention, and his attention was called to a letter in the JOURNAL and NEWS upon the subject. It was decided that the Council report upon the matter.

Dr. Bartolomeu lent a revolving stereoscope containing a collection of beautiful glass transparencies—many by Breeze, which was exhibited at the recent *conferenza*.

Mr. BROMLEY also exhibited a stereoscope and many slides, both glass and paper. He stated, in answer to questions, that many of these were made from several negatives; as, for instance, in a moonlight effect the landscape portions must be placed closer together, centre to centre, than the clouds, and these later nearer again than the moon behind them, in order to secure the stereoscopic appearance.

Mr. SHARMAN brought an enlargement showing the recent excavations at the "Sphinx" from one of his own negatives.

The meeting then adjourned.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The sixth ordinary meeting of the current session was held in George-street on April 6, — Mr. Charles Fraser in the chair.

The minutes of the last meeting were read and approved. Nine candidates for admission as ordinary members were elected, and several nominations were made for election in May.

Mr. ROBERT H. BOW, C.E., read a paper on *Fixing Silver Chloride Prints by Means of Solution of Ammonia* [see page 231], and illustrated his remarks by a large number of silver prints made in the course of his experiments.

A discussion followed, in which Mr. H. Brebner, Mr. Fraser, and others, took part. A vote of thanks was accorded to Mr. Bow, who shortly replied on one or two points.

The CHAIRMAN intimated that, in deference to an unwritten law of the Society, Mr. Forgan had placed his resignation of the Presidency in the hands of the Council. He was about to enter into trade in connection with photography, and, as the members were aware, this had hitherto been regarded as a disqualification for the office; but it had been arranged that Mr. Forgan should retain his position till a suitable successor had been appointed.

A discussion took place upon difficulties occasionally met with in toning silver prints, in which a considerable number of the members engaged.

Mr. WILLIAMS said he had on the whole been dissatisfied with ready-sensitised paper. He frequently found a decided difference between the tone procured from the corners and that from the centre of the sheet. As an amateur he had gone over to gelatino-bromide paper.

Mr. BREBNER had known ready-sensitised paper to be as capable of yielding good tones as any other, but it did not usually tone so easily as that which professionals prepared daily. There was a tone coming into demand having a tinge of crimson in it which was not always successfully got. He found warmer tones more easily had when salt was not used, and he believed toning should be conducted in some degree of daylight.

Mr. AYTON said, with a new bath and no salt used, a warm tone was got which was distinguishable quite from a slightly toned print. If a good previous washing is not given, the hypo fixes out some of the tone along with the chloride.

Mr. BIBBS thought it well to thoroughly wash between toning and fixing. Plenty of water after toning was better than a short immersion in salt solution.

Two questions were proposed for discussion at next meeting, namely, a good test for endurance in silver prints, and a good means of intensification.

The new iris diaphragm as applied to lenses, and a curious old bath camera for wet plates, were exhibited by Mr. J. M. Turnbull.

Newman's patent shutter was exhibited and explained by Mr. J. STEELE.

A large platinum print of a group of distinguished professionals and amateurs, taken at Derby during last year's Convention, was laid upon the table, and for which Mr. Wardale had kindly presented an oak frame. It is to be hung in the Council room.

Mr. A. INGLIS also presented a large parcel of stereoscopic slides of an interesting description.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held in Lamb's Hotel, Dundee, on Thursday evening, the 7th instant,—Mr. Macdougald, Vice-President, in the chair.

A series of lantern slides illustrating the new Tay Bridge was exhibited by Mr. F. C. Caffin, C.E., Resident Assistant Engineer. The slides were from negatives taken by Mr. Caffin during the construction of the viaduct, and illustrated in a very vivid manner the vast difference in apparent stability between the old and new bridges. As each slide was thrown on the screen Mr. Caffin described the process it illustrated, and a great deal of information was given as to the construction.

A number of slides were then exhibited by Messrs. Ireland, Mathewson, and Baird.

The first outdoor meeting of the season was arranged to take place on May 25, the route proposed being by rail to Blairgowrie, then drive to Perth via Marlee, Chung, Melkour, Kinclaven, and Seone.

Correspondence.

Our Correspondents should never write on both sides of the paper.

APRIL MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—GIFT TO THE SOCIETY OF A MAGNIFICENT ALBUM.—DEATH OF M. ROMMELAIRE.—PRESENTATION OF A NEW APPARATUS FOR EXACT FOCUSING AT ANY DISTANCE.—A NOVEL DARK SLIDE FOR FILMS.—M. FABRE ON SUTER'S LENSES.—A NOVEL MODE TO ASCERTAIN THE FOCUS OF LENSES.—A NEW AND ENERGETIC DEVELOPER.—GELATINO-CHLORIDE OF SILVER EMULSION.—AN EXACT SYSTEM OF MEASURING THE RAPIDITY OF OBTURATORS (RAPID SHUTTERS).

The Photographie Society of France held their monthly meeting on Friday evening, the 1st instant, M. Bardy in the chair.

M. Lemercier offered a magnificent album of views taken by him in Algiers and Tunis. The Society accepted with thanks this liberal offer.

The death of M. Rommelaire was reported; the Chairman expressed the grief felt by the Society for the loss of one who had done so much for the progress of photography.

M. Jeanmaire presented a new kind of finder, or, as he calls it, an apparatus for focussing immediately at any distance. The apparatus is fixed on the top of the camera, and resembles the mouth of a crocodile. By a system of leverage, as soon as the operator touches the screw of the lens, in order to focus, if the front of the lens go outward the mouth of the crocodile opens, and the distance between the teeth of the upper and the lower jaw gives the distance. Supposing that the instantaneous picture of a steamboat be required, the boat being two hundred yards distant, the operator can focus his lens for that distance without the aid of a focussing glass, by knowing how far open the jaws of the apparatus ought to be open for that distance. The next service which these jaws render, and which, perhaps, although coming in second rank, is the most useful, is that the distance of an ordinary sized man from the camera can be judged at once. When the jaws are full open, if the head and the feet of the man come exactly between two of the teeth of the apparatus he may be said to be ten yards distant, if his image be so small as to come between the two first teeth he is two hundred yards from the camera, and so on in mathematical proportion.

M. A. Blazy presented a new form of dark slide for films, which I consider very ingenious. I will endeavour to describe it fully if, peradventure, it may be of service to any of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY. The dark slide is made in the same fashion as the ordinary single slide, only a little thicker, so as to leave room for fifty or sixty films. On the back or the side opposite to the exposing shutter is a box the whole width of the shutter, but not so long. Through the centre of this box is a drum or axle, upon which can be wound many films. To this revolving drum is attached a crank handle, placed on the exterior of the box. Now what follows is novel. The film maker conceived the idea of making use of his packing paper to keep the light from his films and to serve in the exposure. We must now suppose the slide to be for $6\frac{1}{2} \times 4\frac{1}{2}$ films. He takes a piece or strip of black paper four and three-quarter inches wide, but several yards long if necessary. This paper is folded in lengths of six and a half inches. In each of the folds of the paper a sensitive film is introduced and gummed or pasted. When all the folds are closed very little room is taken up. The block is put into the dark frame, and the beginning of the black paper is pulled down; a film is then visible. This is placed upon the glass of the dark

slide, and the end of the black paper is wound round or fixed to the drum. The back of the dark slide is now closed and a screw is wound up, which moves forward the back board and pushes the film against the glass. The proper exposure is given, then the screw is loosened, the crank handle is turned, the paper bearing the film is wound round the drum until the second film is in front of the glass, the screw is again wound up, all is again ready for exposure, and so on until all the films have been exposed. A little criticism was not wanting as to the advisability of putting sensitive gelatino-bromide of silver preparations between paper—not only putting them between, but pressing them one against the other. The author said, that if chemically pure paper be employed no chance of accident could occur. Time will prove the value of this statement.

M. Fabre exhibited some Suter lenses, and gave a short history of photographic optics. The readers of THE BRITISH JOURNAL OF PHOTOGRAPHY are so well up in this subject by the pen as well by the lectures of the Editor, Mr. Traill Taylor, that it would be superfluous to give this lecture in full.

M. de la Baume Pluvinel, a gentleman attached to some observatory, I am inclined to believe, gave a method he had discovered of measuring the focus of photographic lenses. He finds that the most convenient method is to photograph the constellation of the Great Bear, and by measuring the angles given the focus of any lens could easily be ascertained. Many interesting negatives of this and other constellations were shown. M. de la Baume Pluvinel regretted that no blackboard was at hand, so that he could show us how these calculations are made. Decidedly, if we are obliged to study astronomy to know the focus of a lens, we may be obliged, sooner or later, to seek its manufacturer in the moon.

M. Lumiere drew the attention of the Society to the hydrosulphides as developers. It appears that their developing energy is something wonderful. It has often been said, that however rapid may be the exposure, sooner or later a developer would be discovered with which all details can be brought out. According to the negatives shown us, this desideratum has been attained. Instantaneous stereoscopic images on one side, developed by the ferrous oxalate or by the pyro, showed feeble images, whereas on the other side (with the same exposure) all details were out and a vigorous negative could be seen.

M. Tondeur exhibited lantern slides obtained by his gelatino-chloride preparations.

M. Londe gave a lecture on his method of measuring the rapidity of instantaneous shutters. He employs a diapason or tuning fork, with electrical apparatus to obtain the vibrations. On the tuning fork a quill pen is attached. This marks the vibrations during the exposure upon a glass plate blackened by means of a smoking lamp. This glass plate falls at a given rapidity, which makes an undulated line more or less open, according to the number of vibrations per second, or the rapidity of the fall of the blackened glass. M. Londe, as near as I could glean, fixes to the top of the tuning fork a square in metal, having a small hole in the centre; upon this hole is brought to play a very powerful light. Now, if a sensitive glass plate be placed behind this hole and exposed a point would be the result in the negative, but if the glass plate were allowed to fall a line would result. If, on the other hand, the diapason were made to vibrate the line would be undulated. As the number of vibrations of the tuning fork is well known, it is very easy to calculate the length of time that the light passing through the dark shutter had acted upon the sensitive plate. If the exposure had been rapid the undulations would be very few, so that by measuring these undulations the exact rapidity can be ascertained. Projections from the magic lantern of undulations obtained by different shutters showed the value of the apparatus of M. Londe.

PROF. E. STREIBING.

WAXED PAPER MEDIUM FOR STUDIOS.

To the EDITORS.

GENTLEMEN,—Acting on your suggestion in last week's "Answers to Correspondents," for the information of Mr. A. Brown, and others, who have found a difficulty in obtaining the right sort of paper for softening the light in their studios, I beg to state I had the paper made for me by Messrs. C. J. Jeffries, Wholesale Stationers, Bristol, price 8s. per ream.

Those of our fraternity who are troubled with the direct rays of the sun will find it a great boon, or to those who are obliged to submit to the nuisance of high buildings cutting off a portion of their light, the use of the paper will be found to diffuse and equalise the light. As a proof of rapidity, I took several fully exposed negatives in one second exposure each with a Wray's rapid rectilinear this morning.—I am, yours, &c.,
35 and 36, Wine-street, Bristol, April 9, 1887.

T. PROTHEROE.

THE RIGHT TO THE NEGATIVE.

To the EDITORS.

GENTLEMEN,—I do not profess to be a "high authority," or even "an authority," but with your kind indulgence send you what to me seems the proper way of looking at this question.

With deference to you, Gentlemen, and your correspondents, I do not think the claim mentioned by Mr. A. Debenham is either "unjust," "ridiculous,"

or "preposterous." The essence of the dispute is, Did the 25s. named include the total cost of the production of the negative? Answering this question fairly and honestly covers the whole matter in dispute. If the 25s. included—as I think the charge generally made for photographs does include—the cost of the production of the negative, clearly the negative, in law and equity, is the property of the purchaser, no matter what hitherto has been the custom in the photographic profession as to retaining the negative.

I would respectfully suggest, Gentlemen, that the analogy you make in your editorial of the 1st instant is no analogy at all. Putting composite photography on one side, a portrait negative can only be used for the printing of the portraits of one person. Types may be, and are, used for the printing of many things. The true and correct analogy is in what the author has to pay for the "setting" or "composition" of the types.

Types are "plant," and although it may be commonly supposed to be correct, I should like to see by what process of reasoning or law negatives—the production of which has been paid for by customers—can be legitimately considered as "assets."

Is not this matter of right to the negatives on all fours with the case of *Vere Foster v. Marcus Ward & Co.*, decided in the Irish courts a year or two ago? It was then decided that Foster, having paid for the production of certain drawings, which were on lithographic stones, was entitled to the possession of the stones with the drawings on, on tendering the market value of the stones, i.e., so much per pound weight. I think so.

Here is a parallel instance from the printing trade. A client may request an engraver and printer to design and engrave a business card, from which, say, one hundred cards are printed. As this plate may be used for such client only, of course he is charged with the cost of designing and engraving in addition to the cost of cards and printing. Now, although it is quite a common custom for the printer to retain possession of the copperplate, the printer would never dream of refusing to deliver up the plate to the client when requested to do so, and still less would he venture to reckon the said plate as an asset in his estate.

There is no hardship here, neither can there be in delivering up a negative for the production of which a photographer has been duly paid.

Mr. F. A. Bridge's method of meeting the difficulty raised might be effective in disposing of the negatives as negatives, but does not touch the matter of the "right to the negatives."—I am, yours, &c.,

28, 1 royn-street, Manchester, April 4, 1887.

G. A. RATRAY.

COLONIAL GRIEVANCES.

To the Editors.

GENTLEMEN,—Your insertion in THE BRITISH JOURNAL OF PHOTOGRAPHY of the accompanying "resolution" will much oblige. Many of our members feel much hurt at the implications contained in the article, and the matter was thoroughly discussed at the meeting named, when much spirit was shown amongst those present (a large meeting), and the accompanying resolution was unanimously adopted. I shall therefore feel grateful if you will find space for it in the earliest issue after receipt.

—I am, yours, &c.,

CHAS. M. ALLEN, Hon. Sec. Q.P.S.

Diocesan Registry, George-street, Brisbane, February 28, 1887.

At a General Meeting of the Queensland Photographic Society, held at the School of Arts, Brisbane, on the 19th of February, 1887, the following resolution was unanimously adopted, and the Secretary instructed to send a copy thereof to the Editors of THE BRITISH JOURNAL OF PHOTOGRAPHY, with the request that they would kindly publish the same:—

Resolution.—"That this Society, having read and discussed the article which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY dated the 31st December, 1886, over the signature 'Monitor,' desires to formally express its disapproval of the strictures therein contained, and to protest against the implied unreasonableness of the orders sent home by members for goods, and the general tone of the said article, as unwarranted, uncalled-for, and having a tendency to mislead your general readers, who are unacquainted with the Colonies."

To the Editors.

GENTLEMEN,—Being the party referred to in the Queensland Photographic Society's report, whose order had been so unsatisfactorily treated by a London dealer, and the mention of which "Monitor" runs foul of in his "Echoes" in your JOURNAL of 31st December last, I heartily thank you for your footnote to his effusion, as I fully appreciate the disadvantage at which I am placed in replying to the article.

"Monitor" gives rein to his imagination and is righteously indignant at the mere thought of such a charge being made against London dealers, for all of whom he entertains so high an opinion that it would be impossible for any of them to so sin through sheer carelessness or intentional neglect, and travels from Dan to Beersheba to find instances of foolish orders being sent them by parties who seem to think that it is but "a hop, skip, and jump" from one part of London to another.

On examination it might be found that the writer knows London as well as, if not better, than "Monitor," and when he learns the particulars of the case referred to he might tell us whether it was "sheer carelessness," intentional neglect," or if a stronger term would not be applicable to it.

The order for the goods, with the money, was sent on October 23, 1885. The mail usually takes rather less than six weeks between this and London. Acknowledgment of receipt of the money is dated January 30, 1886, and apology made for the delay, stating that the apparatus was then ready for packing and that the whole would be sent by next steamer. Nothing further was heard of it by May 9, when I wrote, if any difficulty in supplying the odd things, such as a few printing frames and the like, which any dealer would be supposed to have in stock and intended to make up the even money, to send off the apparatus advised on January 30, as being then ready without them. No notice was taken of this, so I wrote on August 27 threatening legal proceedings through a friend if goods not promptly despatched or money refunded, at the same time advising my change of address. On November 19 the bill of lading and invoice were sent with the case to my old address, seven hundred and fifty miles from here, and on November 26 the dealer says, "I now send duplicate bill of lading and have the great mortification to find that the case was by my fault sent to Mackay instead of Brisbane. How to explain all the long series of mishaps and delays have occurred to me I hardly know, except I have been out of my senses, which is probably true, for I have had worries enough to cause it." This is all very well, but unfortunately my experience with this firm is not singular, as friends when they heard of the order sent said—"I did not know it as well as they or I certainly would not have entrusted them with it." I received the case on January 16, 1887, within a week of fifteen months from the date of the order!

When any one writes to the papers it is but natural to expect that he knows something, however little, of the subject on which he discourses but when "Monitor" refers to the facilities we have in Brisbane for getting apparatus, or the general run of photographic material, it is quite evident he is grievously ignorant of how we are situated in this respect, unless he intended his remarks, as Artemus Ward would have said, "for sarkasm." The selection here is miserable in the extreme, and the prices almost prohibitive. It is not the saving of simply a few shillings, as anything we can get here is from fifty to one hundred and fifty per cent. dearer than in the old country. The treatment, however, our orders have already received does not encourage us to go into photography as we should like. Seven months since money was sent to the author (no publisher named) for a copy of a new work advertised in your JOURNAL. Nothing has been heard of it since, although enough sent to amply cover cost of book and postage. Money was also sent by another member of our Society for material for a well-known process, and the parcel asked to be sent by either of two routes. After considerable delay the invoice arrived about six or seven months ago, but neither shipping receipt nor other advice about it. Of this, too, nothing further has been heard. Another member had a large order sent home, and in due course received an array of paper and films which had never been seen here before. What they are or how to use them there is not the slightest information outside or inside the packages. If such cases have occurred amongst my own small circle, what must have happened to the fraternity in general scattered over the whole world? Yet the whine goes up continually about Colonials sending to the Continent and America for merchandise because they are promptly and often better served. Let "Monitor" induce some of the dealers he knows so intimately to cultivate this unoccupied field at least by square dealing, and I do not think there will be any cause for regrets; but at the same time kindly ask him not to run away with the notion that it is but "a hop, skip, and jump" between Brisbane and the capitals of the other Australian colonies.—I am, yours, &c.,

D. S.

Moreton-street, Brisbane, Queensland, Australia, February 21, 1887.

[We sympathise with our Colonial brethren in the treatment they have received from certain dealers, and publish their letters in the hope that it will lead to a prompt reform. We cannot but feel sorry that the large and honourable body of London dealers should have to suffer through the unwisdom (to put it mildly) of one or two of their number.—EDS.]

ENAMELLED IRON REFLECTORS.

To the Editors.

GENTLEMEN,—At the last Technical Meeting of the late South London Photographic Society, a very excellent white enamelled iron reflector of the usual shape was exhibited by the "Permanent Enamel Company," Plaistow.

The reflecting power of this pure white surface appeared so great that I determined try a few experiments with it, the result being that for most purposes I found it infinitely superior to the usual silvered surface, whether on copper or glass. This led me to suggest to the Company the desirability of their making plain sheets of white enamelled iron, which could be used for many photographic purposes. An experimental sheet of about eighteen inches square was ordered, and this has equalled, if not surpassed, my most sanguine expectations.

Whether as a simple reflector in the studio—an outside reflector for equalising the light over a negative or transparency to be copied—or merely in place of the sheet of cardboard or looking-glass in the retouching desk, I have found it by far the best reflecting surface I have

tried. Atmosphere has no effect upon it, and a damp sponge will at all times make it equal to new.

I understand such sheets could be made of almost any reasonable size at a cost of about 2s. 6d. to 3s. per square foot, and if two or three sizes could be decided upon as likely to be of most general use, and kept in stock at our photographic warehouses, they would doubtless find a ready sale.—I am, yours, &c.,

F. A. BRIDGE.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange a fifty-two inch bicycle (medium) for a rectilinear lens.—Address, H. EASON, High-street, Chipping Norton.

Wanted, rolling machine: will give value in ten-inch burnisher and background, exterior.—Address, J. MAJOR GREENWOOD, Brighouse.

Wanted, whole-plate camera in exchange for fifty-two-inch bicycle, by Stanley, Coventry.—Address, H. RIDLINTON, East Gate Studio, Warwick.

Wanted to exchange, a 12×10 portable lens, by Perkin, Son, & Rayment, for a 12×10 rapid rectilinear, by any good maker.—Address, EDWARD A. RICE, 50, Warner-road, Camberwell.

Wanted, fancy studio screen in exchange for seven-and-a-half-feet by six-and-a-half-feet backgrounds, interior and exterior.—Address, O. CARTER, Photographer, 19, Commercial-road, Bournemouth.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

R. MULLER.—The supply of the material has been discontinued.

J. W. (Scarborough).—The lens is a "caution." Is it possible that it can be genuine?

A. G. C.—Of course the paper must be fumed before it is printed. The paper must be dry before it is fumed.

T. B.—The green colour indicates the presence of copper as an impurity. Weaker acid may be used if it be pure.

A. B. C.—See reply to "Inquirer." You have no right whatever to pirate any copyright photograph whether for sale or otherwise.

A. R. F. E.—The spot is the well-known flare or ghost spot. It can be avoided by altering the relation between one of the lenses and the stop.

A. W. RANKEN.—There will, practically, be no difference between the two. The term "fifty times" or any other number of times simply means anything or nothing; the sensitometer number is what you must be guided by.

J. WHITFIELD writes: "Is it not desirable to make known that in using metabisulphite of potash, as recommended by Mr. Pringle, half a drachm of 'SSO ammonia is neutralised and made non-effective by each drachm of the salt employed? If this is not calculated for, the method won't be entirely 'rational' after all."

W. T. BARKER.—1. Separate the tube in the middle, lay aside the posterior portion, and insert in its place the front half, by which the front lens will assume a reverse position. Then employ a stop, for which there is doubtless a receptacle.—2. The alum solution may be prepared as you have been doing.—3. Earthenware dishes are the best that can be employed for the bichromate of potash solution. Tin is, however, often used for the purpose.

INQUIRER will be glad of answers to following questions: "Am I infringing the law by photographing for myself (copies not for sale) a copyright engraving lent by a friend, without any payment whatever? Also, how long do copyrights last?"—If our correspondent copies any copyright work he renders himself liable to the penalties for the piracy. The copyright in a photograph, according to the existing Act, endures for the lifetime of the author and for seven years after his death.

JUBAR.—The cause of your failure in taking large heads with the front lens of a portrait combination is evidently due to your attempting to use one of too short a focus, hence it had to be approached very close to the sitter. Of course the single lens has to be stopped down considerably in order to secure good definition, consequently it will be much slower in action than the combination in its entirety. The diagrams you refer to have so frequently appeared in our back volumes and ALMANACS that it would be a waste of space to be continually repeating them.

BLUCOSE writes: "Wishing to introduce a club portrait into my business, to be uniformly a bust portrait, vignette—the size I have not decided on, but will be 16×20 or 18×22—I am undecided which would be the best to introduce, bromide enlargements or photo-crayons. I am acquainted with the first, but have never seen any pictures made by the second (photo-crayon) process. Would you kindly inform me which would be the best for the purpose—that is, which process would make the nicest-looking enlargement from an ordinary negative? By kindly answering the above through your 'Answers to Correspondents' column you will greatly oblige."—In reply: The bromide pictures, in your hands, will doubtless prove the more satisfactory of the two; they lend themselves better to colouring and finishing in monochrome than the photo-crayons.

S. WALTHER says: "I have recently been sensitising my own paper for printing, and find I get much better tones on it than on the ready sensitised I have hitherto been purchasing. I use a fifty-grain bath, but find that the paper will not lie flat on the solution. As soon as it is placed on the solution it begins to curl up, leaving the edges bare for a time. Can this be remedied, or must I obtain a different paper? because it seems to me that the edges—from the fact that they are for a shorter time in contact with the solution—will be less sensitive than the other portions."—If our correspondent will, as soon as the paper begins to curl from the solution, gently breathe on the back it will quickly regain its original position. Another plan is to keep the paper in a slightly damp place for an hour or two before sensitising. The former plan is, however, to be preferred.

C. STEPHENSON.—Our correspondent has lately been seriously troubled with spots upon his prints, although he strictly adheres to the routine he formerly employed when this trouble did not appear. He encloses a print, and asks a suggestion as to the cause.—In reply: Had the print been mounted we might have surmised, from the appearance of the spots, that bronze powder might have been a factor in the case, but this evidently will not apply in the present instance, seeing that the prints are unmounted. They probably arise from sulphur, lime, or other deleterious substance in the water. Spots of this character seem to have been very prevalent of late. With a view to elucidate the matter, we will feel obliged if some of our correspondents troubled in this way will furnish us with details of the circumstances under which they appear.

VIGNETTE writes: "In your 'Answers to Correspondents' could you give me a little information about the inclosed carbon print? I am often troubled with little smears, like inclosed, round the edges of the vignetting. It is very rarely I get any of the marks on full lengths—only now and then on a very bright light in a face. Also at times I have a great difficulty in getting the vignettes soft at the edges. If you could give me a little of your advice you will greatly oblige."—The markings complained of may be due to one of two causes, or the two combined. One is that the tissue, either before or after sensitising, may have been touched with a moist or greasy finger; the other that the tissue was in a too soluble condition when it was used, hence its surface during the development of the picture was in an exceedingly tender condition, and therefore very liable to abrasion with the slightest touch. With tissue in this condition a very slight contact with any deleterious substance—perspiration from the fingers, for example—will enhance the evil. The remedy is to keep the sensitised tissue longer before taking it into use. With regard to the vignetting, it is much more difficult to obtain a soft gradation in carbon than with silver. We consider the example forwarded an unusually good one for double transfer, even when developed on collodion.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, April 20, 1887, will be *Development*.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—The next meeting will take place on Tuesday, the 19th instant, at Myddelton Hall, Upper-street, Islington, and will be a lantern evening. Visitors are invited.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next ordinary meeting of this Society will take place on Tuesday next, April 19, at eight p.m., at the Gallery, 5A, Pall Mall East, when a paper will be read by Mr. James Cadell, *On Mr. Dallmeyer's Proposed Alteration of the Standards for Lenses of the Photographic Society of Great Britain*.

CANADIAN PRICES.—The Photographers of Canada assembled in Convention in the city of Toronto August 17, 18, and 19, 1886, having taken into consideration the present depressed condition of the photographic business throughout the country, desire to call the attention of the public to the following facts:—That the ruinously low prices now prevailing lead to the following results:—1st. Lowering the artistic standard of the work. 2nd. The almost necessary use of cheap materials and accessories. 3rd. The employment of inferior assistance. 4th. The prevention of sufficient time and care being given to the details in the workroom. All of which tends to reduce the permanence, and consequently the real value, of photographs to our patrons.—*Printed by order of the Photographic Association of Canada.*—E. POOLE, Secretary.

A WARNING TO AMATEUR PRINTERS—AND OTHERS.—For the information of photographers, several of whom are amateur printers, if only to the limited extent of printing the names and titles of their pictures on the mounts, we quote the following, sent by Messrs. Elworthy & Co. to the *Coventry Standard*:—"As there are many persons, in the county of Warwick and elsewhere, who use *printing presses*, we beg to inform you that any person keeping or using a printing press, or types for printing, or a maker or seller of types or printing presses, not having given notice and obtained the certificate required, and to be produced when required, is amenable to the 39 Geo. III., c. 79, thereby incurring the penalty of £20, or imprisonment not exceeding six months nor less than three. There is no exception in the Act in favour of *amateur printers*. Moreover, all those persons who use machines or instruments—whatever called—where *types* are a part of the machinery, by which an impression is made, act in contravention of the Act, unless they comply with the essentials of that Act by giving notice and obtaining the certificate required."

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1407. VOL. XXXIV.—APRIL 22, 1887.

AQUEOUS VARNISH FOR GELATINE NEGATIVES.

THE question of varnishing gelatine negatives is one that has exercised the minds of photographers since a very early period in the employment of dry plates, and we question whether it will not continue to be a source of trouble for a long time to come, or until some entirely new preparation makes its appearance.

Naturally in applying a varnish to a negative film one expects it to be a protection, else why resort to the trouble of an additional operation. Yet, strange to say, some varnishes that have been employed for the purpose have proved rather destructive than protective; so much so, indeed, that many photographers we know prefer to print from their negatives without varnishing. Collodion and gelatine films differ very widely in their requirements with regard to protection as well as in the conditions to be observed. Thus, collodion, from its extremely tender nature, absolutely requires a protection of strong, tough varnish to prevent its being scratched, while gelatine, on the other hand, is robust enough in itself to resist the ordinary wear and tear of use. But gelatine, from its strong affinity for moisture, combined with its organic character, requires protection from damp as well as from contact with chemicals, and it is here that the difficulty arises.

In the case of collodion, which is not subject to injury or any considerable expansion from damp, it is a simple matter to apply a layer of tough, resinous matter which answers fairly well the purpose of guarding its tender surface; but that layer, though hard, is neither elastic nor is it impervious to moisture, two conditions that are pre-eminently required either singly or together in a perfect varnish for gelatine films. Consequently, when such a varnish is applied to gelatine it is, in the first place, no protection against damp, which penetrates through the *quasi*-protecting layer, and is absorbed by the gelatine beneath. Then the non-elastic nature of the varnish commences to operate as an absolute injury to the negative, for as the underlying gelatine film swells under the action of the moisture it has absorbed—and this, as all very well know, it will do to a very considerable extent and in a very short time—the non-elastic covering of resins is cracked and rent in all directions, rendering the negative, if not permanently useless, in all cases at least temporarily so, until the varnish is removed and replaced.

The want of damp-resisting qualities also renders such resinous varnishes useless as protection against chemical staining, a danger to which negatives which are much printed from are peculiarly liable from constant contact with silvered paper possibly slightly damp. This, as is well known, gradually but surely develops spots and stains of a reddish brown colour,

which entirely ruin the negative, and which are extremely difficult, and in too many cases impossible, of removal.

Another point of difference between collodion and gelatine is found in the fact that while the porous film of the former readily absorbs the alcoholic solution of gum resin employed as varnish, the horny and impervious gelatine film entirely refuses it. Consequently, while in the one instance the varnish is incorporated with, and forms part of the film, the one helping the other and adding to the protective power, in the case of gelatine the two layers remain isolated, and, except for surface contact, independent of one another. Each then retains its individual properties unmodified, as in the previous instance, by the mutual support given by one to the other, and as a result the gelatine preserves its affinity for moisture and its capability of expansion, and the varnish its natural brittleness.

Collodion, long since recommended and used as a substitute for, or an accessory to, ordinary varnish, is free from at least one of the faults of the latter, and has, therefore, secured a large share of favour. It is true it is not impervious to moisture, and, consequently, cannot act as a waterproof protection to the gelatine film; but it is at least sufficiently elastic to "give" to the swelling of the gelatine if the latter should become damp. In fact, by its expansion and contraction with the underlying film it is employed to protect, it obviates the difficulties experienced from the cracking of the more brittle varnish. Moreover, it is not unlikely that by suitable additions—as, for instance, of castor oil—it can be made far more impervious to damp than resinous varnishes; at any rate, it is found practically to be superior as a water resistant.

But, like resin varnishes, collodion lies completely upon the surface of the negative film, the gelatine refusing entirely to absorb it, and its protective influence against scratching and other rough usage depends therefore upon its own natural toughness, and not upon any binding together and consolidating of the particles forming the image or film, as in the case of collodion. What we want is something that will be absorbed into the gelatine film and when once dry become insoluble in water, and so, by isolating the particles of gelatine, render it non-absorptive and inexpandible. This *desideratum* is probably unattainable, at least in its strict entirety, but we may perhaps partly secure the desired result. A natural way out of the difficulty that will suggest itself is to render the film insoluble by chemical action, but unfortunately, as is well known, though it is perfectly easy to "insolubilise" gelatine in the manner referred to, the treatment does not prevent its absorbing water and consequently expanding more or less.

A suggestion that has been made more than once in the way of a remedy for this state of affairs consists in the employment

of an alkaline aqueous solution of shellac, though, so far as we know, it has not obtained very general adoption, if it be followed at all. Shellac, either bleached or unbleached, dissolves with great readiness in solution of borax or the alkaline carbonates, and when the solution thus formed is evaporated to dryness the residue is said, though not with perfect truth, to be insoluble. At any rate, it is sufficiently so to make a useful "waterproof" protective varnish for many purposes when the alkali is not an objection.

We have recently been experimenting with solutions of this character applied to gelatine negatives, and we are inclined to believe that, though perhaps not forming a practically perfect protection such as we have indicated, they are likely to be used with advantage. The aqueous lac varnish is, as may readily be supposed, not so durable by a long way as the alcoholic, especially when applied to glass or other impervious substances; but our experience with it is that, when applied to paper or other surfaces capable of absorbing it, it forms a much tougher protection than the alcoholic solution when maintained on the surface. Thus, a gelatine negative, varnished with aqueous solution of bleached lac, presents a harder and less easily scratched surface than one protected by an alcoholic varnish of unbleached lac, the latter being itself naturally harder in the unbleached state. In the one case the lac is absorbed into the film of gelatine, in the other it is not, and though the first—the lac-impregnated film—is not waterproofed, or rendered non-absorptive, it is, within certain bounds, dependent upon the strength of the varnish, capable of swelling and contracting under the influence of moisture without cracking in the manner an alcoholic varnished film will do.

The solution we have found to answer best, after trying various combinations and strengths, is composed as follows:—

Bleached lac	2 ounces.
Borax	$\frac{1}{2}$ ounce.
Carbonate of soda	1 drachm.
Glycerine.....	30 minims to 1 „
Water.....	20 fluid ounces.

Dissolve the borax and carbonate of soda in ten ounces of hot water, and throw in the lac broken into small pieces; place the containing vessel upon a clear fire, or over a gas stove, and stir until the lac is dissolved.

When dissolved, allow it to cool partially, and filter through filter-paper, after which the glycerine is added and the bulk made up to twenty ounces. Though now apparently perfectly clear, if it be set aside for a few days a sediment will be thrown down, when it may be again filtered, and then comes off beautifully bright and of a light amber colour.

To use this varnish the negative is finished, washed, and dried in the ordinary manner; it is then carefully dusted and either immersed in the varnish in a dish or the varnish is poured on to it and allowed to soak in for about a minute, after which the plate is closely drained. Under the action of the varnish the gelatine swells and absorbs the dissolved shellac, which, penetrating the film, renders a thick surface-layer unnecessary; indeed, it is preferable to drain as closely as possible. In two or three minutes the moisture will have been completely absorbed, and the surface of the negative takes a smooth, glassy appearance, showing the image in very slight relief. In the course of half an hour, at ordinary temperatures, the varnish will have dried to a perfectly smooth and beautifully even surface resembling glass itself, and presenting extreme hardness to the touch. If a thicker solution

be employed than the one given the result is not so satisfactory.

If the film so varnished be plunged into water, it will swell just as if unvarnished, but if set aside to dry spontaneously it will do so with perfect uniformity and without any of the cracking so well known in connection with an alcoholic varnish. If heat be employed, or if the solution be stronger than that given, cracking will most probably occur.

Though this appears to form an extremely tough and promising protection, we are unable to speak as to its actual durability as yet. A second coating, however, of thin alcoholic lac varnish, or of collodion, would, however, seem to offer an additional amount of permanency if the alkaline lac should show any tendency to deterioration.

PHOTOGRAPHS OF MACHINERY.

THE facility with which gelatine plates have enabled this class of work to be produced has tended to obscure the question of high excellence of results, which we take it should be the aim of every worker. The result is that though difficult subjects have been secured—subjects heretofore impossible of achievement—the general average of such photographs, at any rate of those which have come under our notice—and they have been by no means few—is no advance upon the wet plate work of twenty years ago, and in many instances there is a distinct retrogression to be noted. This is as unfortunate as, in our opinion, unnecessary, and it is worth while to elucidate the causes, in doing which we may suggest a remedy.

In many large machine shops a photographer forms part of the permanent staff, and he, if any one, should be able, by reason of the facilities he possesses, to make the best pictures of the kind it is possible to produce. But the majority of photographs of machinery are made by those who have had little experience of the work. The readiness of production is familiar nowadays to every one, and, consequently, the photographer is sent in for every little piece of work the maker takes an interest in or wishes to have copies of, though a dozen years ago it would never have occurred to him to have for his purpose anything but a woodcut from a drawing executed in the drawing office. In other words, this kind of work was in fewer hands, mainly those who made a speciality of it, and had gained experience of its requirements. One of the most successful men at photographing machinery that we ever heard of was a photographer in the north, who often actually made his negatives without either dark room or tent. He used to go to some dark corner of the place, and by one means or another so screen his plate that he never was troubled with fog, and he obtained most beautiful pictures.

The fact, however, remains that dry plates will be the plates of the future, hence it is now futile discussing questions of wet collodion, and the mode of obtaining the best results from the former is all that need occupy us at present. It must be observed at the outset that the plates best suited for portraiture are not those to be selected for use with machinery. In the earlier days of gelatine plates a slow kind was offered by most of the manufacturers, though we do not often now see them in the lists. Failing such kinds, every photographer must use his judgment, and the direction to look is for a plate that has a great thickness of film, and in which the image shows as little as possible at the back after development. This care is not always necessary, but the operator who has had more than one or two single experiences of such photographing, knows by pain

ful experience that occasions will happen when some particular machine he has to take a negative of is backed by a window, or even a brightly illuminated whitewashed wall. When this is the case his negative will be almost useless unless he have the right kind of plate; for there will be a local foggingness—be it called “halation,” or what one will—that will spread for from half an inch to an inch or more on all objects in the vicinity of the window, an effect that will be intensified by the long exposure usually entailed by the commonly experienced dim illumination of the machine in the only place in which it can be taken.

Coating the back of the plates beforehand by a collodion containing aurine and eosine will very materially assist in reducing the amount of this spreading of the light; indeed, for the work this coating should be given to every plate; but with an unsuitable film the best results will not even then be possible.

It not unfrequently happens that a whitewashed wall forms the only background, and it introduces difficulties not easy to surmount. Whether owing to a general diffused illumination reflected from the back of the plate, or from the whiter surface of bromide plates being more actinic, and, when illuminated with a large space of white, reflecting from some of the lens surfaces sufficient light to cause general fog, or from other occult causes, we will not now attempt to determine, but it will be found that a picture free from fog will under the conditions be rarely produced. The best mode of avoiding the evil is to screen the lens on all sides with a piece of black velvet so disposed as to cut off from the field of view every portion of the white surface which will not be included in the negative. Where it is intended afterwards to paint out the background entirely, as is so often done in this class of work with the idea of making the machine stand out better, it will be advantageous to bring up the velvet within close proximity to the outlines of the machine, as shown by the image on the ground-glass. A little extra trouble will be thus entailed, but the enhanced beauty of the result will justify the slight expenditure of labour. It is surprising how many otherwise good negatives are evidently spoiled through this simple cause—a wide expanse of white background.

Passing now to the practical details of manipulation and exposure, we may say that a gentleman who has had much experience in the kind of photography we are discussing informed us that a camera with a folding tailboard would be practically useless to him. “You so often,” he said, “find yourself crushed up into a corner in order to get any distance at all between camera and machine, that the space wasted by an unoccupied tailboard would often be sufficient to prevent my getting a picture of any sort. But, besides that, one only wants to try once to find out the impossibility of getting all parts of a machine in correct focus if there is a quarter of a yard of tailboard under one’s chin, and a machine before the lens looking about as bright as a piece of coal in a cellar, as is so often the case with these things. You must have a camera with the ground-glass utterly unimpeded, and do your focussing from the front, as with the best forms of studio camera. Further, if you have a rack and pinion focuser instead of an endless screw, considerable gain in ease of working will be secured.”

These remarks seemed to us so pertinent and practical that we have not hesitated to give them in full. The relation of the same gentleman’s experience also of camera stands will be very useful, as it is evident that the selection of one of suitable form is a matter of great importance. He strongly advises the

use of indiarubber caps to the ends of the legs, as it often happens that the only standpoint is upon a heap of iron, upon which the pointed iron shoes of the tripod will not bite. A stand of Kennett pattern, or a modification such as Roueh’s, is a *sine quâ non* from the power of obtaining variations of elevation without extreme spreading of the legs, which would often be impossible, and from the facility of adjusting to awkward standing places afforded by the power possessed by this form of shortening a leg when needed.

As we have in this brief essay left untouched questions of development and so forth, and the after treatment of negatives, we will not now dismiss our subject entirely, but will hope to return to it at some time in the near future.

HER MAJESTY has been pleased to issue a new Commission to inquire into the recent changes which have taken place in the relative values of the precious metals. It will, we are told, devolve upon the members to specially inquire whether the changes of value are due to the depreciation of silver, to the appreciation of gold, or to the two combined. We wonder if the large consumption of silver in photography will be taken into consideration by the Commission, as it now amounts to very many tons annually throughout the world. It should be borne in mind that by far the larger proportion of the silver used in photography is actually consumed, and finally lost as “silver,” which is not so with any other purpose to which the metal is applied. Whatever may be the report of the Commission, consumers of the nitrate will be very unlikely to regret the depreciation in the value of silver. Dry plate makers, and those who manufacture the ready-sensitised papers, we are sure will not.

THE following seems outrageous, but our information comes from a reliable source. A well-known amateur, on a recent visit to Deal, went to the pier with his apparatus, and tendered the usual toll. He was then informed that if he took his camera with him the toll was *ten shillings and sixpence*, but after the first visit subsequent charges would only be three shillings and sixpence. As no notice of any special toll to photographers was to be found at the gates, an explanation was demanded. The explanation was to the following effect. The local photographers had represented to the authorities that amateurs, by photographing from the pier, were causing injury to their business—hence the impost. The amateur was furthermore informed that an operator from one of the large publishing houses had, a week or two before, paid the sum mentioned for the privilege of planting his camera on the pier. He also learnt that, a short time back, an amateur who was unaware of this nowhere-else-to-be-found regulation passed on to the pier with a small apparatus, unnoticed by the toll taker, and had taken two or three pictures, when he was actually compelled by a local photographer, aided, we believe, by one of the pier officials, to draw the shutters of his slides and expose the plates to light, because he objected to pay the half-guinea charge. We know many amateur photographers, of not very extraordinary *physique* either, who would not have submitted to this outrage without a vigorous protest. If this kind of trade unionism pervades the district generally, there is small reason for wonder that Deal is so comparatively little visited as a pleasure resort.

FROM the earliest period of photography it has been a disputed point as to whether the light is, or is not, much less actinic in its character when the wind blows from an easterly than from any other direction. Be this as it may, photographers have for a long time past had ample opportunity of judging the effect, if any, that it has upon the exposure. It is seldom that we experience such a prevalence of east winds, and for so long a time, as we have of late. However, a slight variation in the actinic power of the light is far less noticeable now than it was when collodion, either wet or dry, used to be employed.

ABOUT this season of the year the light usually reaches its maximum in actinism. Every experienced photographer knows quite well that

the briefest exposures are obtained after a sharp April shower has passed over. Not only is a shorter exposure secured, but, in the opinion of many, a sharper, crisper, and a more brilliant picture is obtained. Beginners in landscape photography are apt to be misled, as to future work, by the light under the existing conditions. An apparently fully-timed negative may now be taken with a very short exposure, owing to the trees being devoid of foliage and the branches and twigs standing in bold relief against a bright sky as a background. But, later on, when the trees are covered with leaves, the light, though to all appearance as bright or even brighter, will be less actinic; then similar exposures will prove totally insufficient to obtain good negatives.

EVIDENTLY a great deal of misconception exists as to the meaning of copyright. Several inquiries have reached us of late asking if it be against the law to copy pictures which are copyright, provided the copies are not sold. Of the moral side of the question few, we imagine, will have any doubt whatever. The legal side is made perfectly clear by the Act, which is specially framed to give protection against piracy in any form, and for any purpose. Clause 1 stipulates that the owner of the copyright "shall have the sole and exclusive right of copying, engraving, reproducing, and multiplying such painting or drawing and the design thereof, or such photograph and the negative thereof, by any means and of any size," &c. In Clause 6 occurs the following:—"If any other person, not being the proprietor for the time being of copyright in any painting, drawing, or photograph, shall, without the consent of such proprietor, repeat, copy, colourably imitate, or otherwise multiply for sale, hire, exhibition, or distribution, or cause or procure to be repeated," &c. And further on, that "such person, for every such offence, shall forfeit to the proprietor of the copyright for the time being a sum not exceeding ten pounds; and all such repetitions, copies, and imitations made without such consent aforesaid, and all negatives of photographs made for the purpose of obtaining such copies, shall be forfeited to the proprietor of the copyright." These quotations will answer several queries which have recently been put, more fully than we could do in the columns devoted to answers to correspondents. It may be mentioned that the copyright in any picture lasts during the lifetime of the author of the work and for seven years after his death.

LAST year we directed attention to the fact that the French Government would not permit photographs or sketches to be made in the vicinity of any of their fortifications, and that any one infringing this law, though ignorantly, might subject himself to inconvenience. It now appears that our War Office has followed the example set by their French neighbours, and issued orders to all officers in command of troops, and especially where there are fortifications or earthworks, that under no circumstances are persons to be allowed to make sketches or take photographs of military structures without express permission. It will be desirable for photographic tourists to take note of this, as it may prevent them from being subjected to considerable annoyance.

COLONIAL GRIEVANCES.

I AM extremely sorry that the members of the Queensland Photographic Society should have deemed it necessary to call me to task by special resolution for certain remarks of mine which are alleged to imply "unreasonableness of orders sent home by members (*sic*) for goods." Beyond the fact that the complaint which formed the text of those remarks was made at a meeting of that Society, its members were as far from my thoughts when I wrote as those of any other Colonial body, and the "instances of foolish orders," which I am stated to have travelled "from Dan to Beersheba to find," resolve themselves into one from Canada, and another which I described as from a "foreign"—actually a Continental—firm.

I did certainly go so far as to suggest that there might be some satisfactory explanation of the delay which had occurred in the execution of the one order of which a member of the Queensland Society had complained, and this, in fairness to the large body of English dealers who were impugned, I still maintain I was perfectly justified in doing, knowing nothing of the case one way or another when I wrote and little more now, and making no charge against any indi-

vidual in the matter. The members of the Queensland Photographic Society would have done well before they permitted themselves in their indignant haste to pass a special resolution for my benefit, if they had reflected that they are not the sole representatives of foreign and Colonial photography—my remarks, if they had read them as *carefully* as they appear to have energetically discussed them, referred to both—and they would then have saved themselves, I venture to think, from the somewhat ridiculous position of having fitted on a cap that was never intended for them.

The state of the case appears to be just this. A member of the Queensland Society has been unfortunate in one of his dealings with a home firm, and straightway a general charge is made—in the official report of the Society, mind—against English dealers generally, that if it were not for the slipshod way in which they treated Colonial orders the members of that particular Society would be in possession of more complete apparatus of home manufacture. If the home manufacturers and dealers in a body had protested, I should not have been surprised, and I might have assumed there was some amount of truth in the charge; but as one and all treated it with silence, I can only suppose that, as a body, they felt the imputation lay lightly on them and, no doubt, ejaculated mentally in Shakespearian language, "Let the galled jade wince, our withers are unwrung!" But when an independent voice is raised in defence of a body which, though it may include a black sheep or two, is mainly composed of strictly honourable business men, the framers of the original charge voluntarily take to themselves the rôle of "galled jade" and wince somewhat unnecessarily. For this I repeat I am sorry.

With regard to the letter of "D. S.," who acknowledges himself the author of the complaint, and of whom, by the way, "Monitor" does not "run foul," I need only refer to it to point out that a little more careful reading of my "Echoes" would have saved the trouble of writing it. I am not foolish enough to imagine that intelligent Colonials are sufficiently ignorant of England and its chief cities, to be led away by any such covert allusion to the vastness of London as that contained in the suggestion that it is more than a mere "hop, skip, and a jump" from one part of it to another. As a matter of fact it is, but I did not say so; I said from one end of *England* to the other. I can quite conceive that a dweller in any of the vast Australian colonies may, taking into consideration the limited area of Great Britain and the almost perfect means of communication, look upon it as a very simple matter to obtain, at a day or so's notice, anything that may be required, and with that idea in my mind I wrote of the hop, skip, and jump. "*Paris, c'est la France*," is a well-known proverb, but I am not aware that even the veriest of "Cockneys" would venture a similar claim for London, though "D. S.'s" better knowledge of the place than my own appears to have brought him to that frame of mind. However, independent of whether "D. S." or myself knows his way about London best, I repeat that, in my opinion, it is very unlikely (not "impossible" as he has it) that any of our respectable dealers would lay himself open to such charges as those brought.

One other little inaccuracy I would point out in "D. S.'s" reading of my "Echoes." He says I refer to the facilities in Brisbane for "getting apparatus, or the general run of photographic material," &c. If he will look again, I think he will find that I said it is *impossible* to expect such facilities in connection with "apparatus and goods of special make." So far as concerns "odd things, such as a few printing frames and the like," I should, however, have thought, not knowing anything about it, of course, but only judging from the advertisements of Australian dealers that appear annually in the ALMANAC, that they could be obtained in Brisbane; or that, at any rate, it would be as cheap and more convenient to get them from Sydney or Melbourne, though the distances may exceed the proverbial hop, skip, and jump, than from England.

And now for a final word of advice to "D. S." and others like him, who suffer from this difficulty of obtaining what they require at their own doors except at prohibitive prices. They will serve their own interests better than I could possibly do by attempting to induce, as "D. S." suggests, some of the dealers I know to practically lay themselves out to serve their occasional Colonial customers in preference to their regular home ones. My suggestion is that "D. S." and his friends should show a desire to encourage and promote native

enterprise, and so make it worth the while of Colonial dealers to keep good stocks of at any rate the "general run of photographic materials." If such a desire became evident, the selection of goods would soon cease to be "miserable in the extreme" and prices to be "prohibitive," for the dealer, if he did not manufacture, would be able to buy on better terms, and surely the freight on large quantities of goods would be cheaper than on small parcels for individual use. The same argument holds good with regard to apparatus, though undoubtedly it will take longer to establish the native manufacture; but if the demand arose, I have little doubt but the supply would be there. So long, however, as "odd things" as well as special things are ordered from abroad, it is impossible for the native dealer to keep a respectable stock, and for what he does keep he is bound to charge a price that will recompense him for loss of interest on capital locked up in goods that never sell.

In conclusion, may I express a hope that the members of the Queensland Photographic Society will give the same amount of attention at an early meeting to these lines as they did to my previous remarks, and I will ask them to believe that neither previously nor now has it been my wish to aim a single shaft at any individual or any Society. Except that it is a reply called forth by the Society's resolution, this article might have been written for any other body of photographers.

MONITOR.

DEATH OF J. B. OBERNETTER.

WITH grief do we record the sudden and quite unexpected death of J. B. Obernetter, of Munich, at the early age of forty-seven.

Herr Obernetter's name has been for quite a number of years before the photographic world as a skilled experimentalist of a very practical turn of mind. His more recent efforts were devoted to the preparation of dry plates, on a commercial basis, which should combine orthochromatic with good keeping properties, and in this he had attained quite a gratifying amount of success. He had also completed a method of photo-engraving, of which we have within the past two months seen numerous fine examples.

While we write this we are unaware whether the secret dies with the inventor or if he has communicated it to others who were connected with his business. He leaves a widow and family, who have our deep sympathies in the loss they, as well as the public, have sustained.

THE RIGHT TO A NEGATIVE.

It is well Mr. G. A. Rattray does not profess to be a "high authority," or even a simple "authority," or our faith in authorities generally might be weakened. His knowledge of the printer's business appears to be about on a *par* with his acquaintance with photographic practice, although he discourses so blithely on the subject of types.

"Types are plant," and "types may be, and are, used for the printing of many things," says our no-authority, and, therefore, they do not belong to "the author," who only pays for "the 'setting' or 'composition' of the types." But, on the other hand, "a portrait negative can only be used for the printing of the portraits of one person," and hence your correspondent assumes that it must belong to that one person—the sitter—and not to the photographer.

But the glass upon which a negative is taken can be cleaned, and the silver which composes the image can be recovered, and both can be reutilised for the production of other portrait negatives, *ergo*, by Mr. Rattray's own argument, *they do not belong to the sitter*. Then again, if "the author," as we are told, pays for the "setting" and "composition" of the types only, so the photographer's customer pays for the analogous operations of cleaning, coating, sensitising, exposing, developing, fixing, washing, drying, and varnishing the plate, the "setting and composing of the types," in fact, from which the prints are subsequently produced. And since it is permissible on the part of the printer to distribute his types for the purpose of future use, why should the photographer be debarred from cleaning the glass and recovering the silver used in the production of the plate or "types" for which the sitter, like the author, has not paid?

I purposely confine myself to the photographer's right to destroy the negative as a negative, for clearly he has no more right to employ

it for his own purposes than has the printer to use his formes of type. The negative, I maintain, as representing so much glass and recoverable silver, as distinctly belongs to the photographer as Mr. Rattray admits the types do to the printer. He says, however, that "clearly the negative, in law and equity, is the property of the purchaser;" certainly where there is a purchaser, but by his own arguments I have shown that the sitter, as he supposes, is *not* the purchaser.

Now, let us suppose that the author gives an order for the printing of, say, one thousand copies of his work, for which he is quoted a price; and, further, let us suppose that the printer has sufficient faith in the coming success of the effort to stereotype it on the chance of being called upon to print future editions. Does Mr. Rattray argue that those plates, because they can only be used for printing that particular work, belong to the author? Or does he take the view that, as the metal can be remelted and again employed to produce other stereotypes, it becomes "plant," and as such belongs to the printer? Under the latter circumstances printer and photographer are precisely upon all fours.

The two "parallel" instances quoted by your correspondent are singularly remarkable for their *want* of parallelism or for the marked manner in which they diverge from the lines he has laid down. In the case of Vere Foster v. Marcus Ward & Co., an additional consideration in the shape of the market value of the lithographic stones is mentioned, but in the case stated by Mr. Arthur Debenham this additional consideration is not only not offered but distinctly refused; while, so far as Mr. Rattray's argument is concerned, the offer of payment for the stones is tacit acknowledgment that the first payment does not include the right to the negative.

In the other instance, as is well known, it is the custom of the trade to make a charge for "one hundred cards *and* plate." Unless that be the special contract, I can inform Mr. Rattray from actual experience that he can *not* compel the engraver to deliver up the plate. After many years experience of photography and photographers, I have yet to meet with one of the latter whose everyday contract professes to be to supply "a dozen cabinets *and* negative" for whatever his charge may be.

Special contracts are undoubtedly entered into both by photographers and printers. The printer, for instance, will make a charge in the form of interest on the value of the type if the latter is kept standing, and similarly if the work be stereotyped; or in the latter case the plates may be purchased outright by the author. So, also, with the photographer; but any special arrangement of that description is quite distinct from the ordinary contract, Mr. Rattray notwithstanding.

I am quite unaware what that gentleman's calling may be, scarcely, I should imagine, either photographer or printer; he will, perhaps, give me the *tu quoque* if I advise him to emulate a certain individual and "stick to his last," for I must subscribe myself,

"NOT A PORTRAIT PHOTOGRAPHER."

A SHORT HISTORY OF PHOTOGRAPHY IN COLOURS.*

Beequerel's Experiments in Colour Photography.†—Perhaps the most successful reproductions of colour by means of photography which have ever been made were obtained by the French physicist, Edmond Becquerel, in 1848. Taking a silver plate, such as is used in Daguerreotype, he obtained a thin and very uniform coating of chloride of silver upon its surface. This he sometimes effected by soaking it in chlorine water until the silver assumed a rose tint, or by dipping it into solutions of cupric or ferric chloride. By preference, however, Becquerel placed the silver plate in a solution of hydrochloric acid, and attached to it a wire from the positive pole of a voltaic battery, the wire from the negative pole being fastened to a plate of platinum which also dipped into the acid solution. By this means the hydrochloric acid was decomposed, and the chlorine being drawn, by electrical attraction, to the silver plate combined with it chemically, forming a surface of silver chloride of great purity. As the combination of silver and chlorine took place, the layer of silver chloride gradually increased in thickness, and as it did so its colour

* Concluded from p. 230.

† See *Comptes Rendus*, 1848 and 1854; also *Annal de Chimie*, 1849.

changed to grey, yellow, violet, and blue, and, continuing the action, these colours appeared a second time. When the second violet tint had been obtained, the silver plate was withdrawn from the solution, washed, and dried, and gently heated until the surface assumed a rosy hue. When the spectrum of sunlight or of the electric arc was received upon a plate so prepared, an exposure of a few minutes was sufficient to impress the diverse colours. Coloured images of brightly dressed dolls were also obtained.

Failure in Fixing Coloured Images.—After Becquerel had obtained such favourable results, it may be asked, How is it that further progress has not been made, and why are not coloured photographs more frequently produced? The answer is that no certain means has hitherto been found of *fixing* the coloured images secured; they can only be examined in a faint light, and must be kept locked up in drawers and excluded from the day. They last longer when protected from the air, for oxygen has a detrimental effect upon the colours. Becquerel, however, appears to have succeeded in rendering more or less permanent some, at any rate, of his "heliochromes." One which he presented to Brewster was lent by the latter to J. Traill Taylor, who exposed it to *bright sunshine* without injury to the colours.*

Experiments by the Younger Niepce.—Niepce de St. Victor repeated Becquerel's experiments; but he found it better to form the chloride of silver by immersing the silver plate in a solution of chloride of lime.† He also reduced the time of exposure by coating the chlorinised surface with a solution of chloride of lead in dextrine. Niepce believed that a relation existed between the colours impressed and the source from which the chloride was obtained, and in 1857 he published the results of some experiments on the connection between the colours imparted to flame by certain metallic chlorides, and the colours impressed on silver plates prepared from the same chlorides. Subsequent investigations have not, however, confirmed this theory. Niepce sent specimens of his work to the Exhibition of 1862, consisting of about a dozen reproductions of prints of figures with parti-coloured draperies. Each tint in the pictures exhibited was a faithful reproduction of the original, including yellows, blues, reds, greens, &c., all very vivid. Some of the tints faded at once when these pictures were examined by daylight, but others remained for some hours.

Poitevin obtains Coloured Copies on Sensitive Paper.—In 1868‡ A. Poitevin examined and extended the results obtained by Herschel and Hunt. Taking paper sensitised in the usual way with silver chloride, he washed it and exposed the sensitive surface to light for a short period. The insolated paper was then dipped into a solution containing bichromate of potash and copper sulphate, and finally dried. When such paper was exposed to light beneath a transparent coloured picture—as a painting on glass—the colours of the picture were reproduced upon the paper. Poitevin states that the colours so obtained could be fixed by means of sulphuric acid.

Another French experimenter, St. Florent, in 1874, described§ a method of obtaining similar results in a rather different manner. Paper is soaked, first in silver nitrate and then in a mixture of uranium nitrate and zinc chloride rendered acid with hydrochloric acid. The paper is dried and exposed to light until the surface is slightly darkened; it is then floated on a solution of mercuric nitrate, again dried, and is then ready for exposure to the coloured light whose impression it is desired to secure.

Coloured Copies obtained with Paper—Abney's Researches.—With reference to coloured images obtained upon paper, Captain Abney remarks,|| "It must not be forgotten that pure salts of silver are not being dealt with as a rule. An organic salt of silver is usually mixed with chloride of silver paper, this salt being due to the sizing of the paper, which towards the red end of the spectrum is usually more sensitive than the chloride. If a piece of ordinary chloride of silver paper is exposed to the spectrum till an impression is made, it will usually be found that the blue colour of the darkened chloride is mixed with that due to the coloration of the darkened organic compound of silver in the violet region, whereas in the blue and green

this organic compound is alone affected, and is of a different colour from that of the darkened mixed chloride and organic compound. This naturally gives an impression that the different rays yield different tints, whereas this result is simply owing to the different range of sensitiveness of the bodies."

But the coloured images obtained upon Daguerreotype plates by the method of Becquerel are truly due to the distinct effects of different rays of light, for in that case there is no organic compound present to interfere with the results.

Acting on a suggestion made in December, 1865, by the then Paris correspondent of THE BRITISH JOURNAL OF PHOTOGRAPHY, R. J. Fowler (formerly of Leeds), several trials were made by English experimentalists, and in particular by J. Traill Taylor and G. Wharton Simpson, in the course of the following year to utilise collodio-chloride of silver films in obtaining coloured images. The colours obtained were not so vivid as those secured by Becquerel upon Daguerreotype plates, but they were visible by transmitted as well as by reflected light.

Pretended Discoveries of Photography in Colours.—A year seldom or never passes without the announcement in some newspaper or other that "photography in colours is at last an accomplished fact!" In some cases the "discovery" merely relates to a modification of the well-known mechanical process by which—several negatives being employed—the picture is printed piecemeal, each portion receiving a dash of a separate colour.

Other reputed "discoveries" are due to the fact that by faulty manipulation colours of some kind or other are not unfrequently obtained upon collodion—as in Hunt's example—or even on gelatine plates; or they may be the result of a splitting of the film, giving the "colours of thin plates." Some novice noting these, to him, marvellous appearances, writes in haste to the papers that he has secured the long-wished-for result—a result, however, which he finds himself unable to reproduce.

Still other cases are deliberate frauds. Thus in 1851 an American preacher named Hill obtained almost general credence for his statement that he could produce photographs "glowing with all the colours of nature!" Naturally so wonderful a process was to be called Hillotype. The Rev. Mr. Hill obtained a considerable sum of money by inducing photographers generally to subscribe—payment in advance, of course—for a book which should contain all the details of this startling discovery. After many delays the promised book appeared, but what was the disappointment of the subscribers to find it a mere twopenny pamphlet containing the outlines of the Daguerreotype process, with complications and additions just sufficient to render the obtaining of any picture at all a very improbable matter!

Origin of the Colours obtained upon Salts of Silver.—The most recent researches upon photography in colours are those of Captain Abney.* He states that the colours obtained by Becquerel and others upon Daguerreotype plates are due to the oxidation of the silver compounds employed. When the sensitive plates are exposed in the presence of some oxidising agent, as by dipping them into peroxide of hydrogen before or during exposure, the colours are produced more speedily.

The same investigator points out that there are several known molecular combinations of bromide of silver, which can readily be distinguished from each other by the fact that they absorb different rays of light.

Thus we are acquainted with:—

(1.) A modification of silver bromide which transmits and reflects orange light. This form of the silver bromide molecule exists in paper which has been sensitised with silver bromide on plates coated with a collodio-bromide film, and on collodion bath plates. This molecule will clearly be chiefly affected by the blue rays, since it absorbs the blue end of the spectrum, and work is done only by those rays which are absorbed.

(2.) Another form of the silver bromide molecule appears of a bluish green tint by transmitted light. This modification absorbs the light of the red end of the spectrum, and even the invisible or "dark heat" rays which lie beyond the red. By taking advantage of this property, Captain Abney was enabled to obtain photographs of the

region called the "ultra red," which proved its extension over a length exceeding that of the whole of the spectrum ordinarily visible.

(3.) Silver bromide contained in emulsions which have been boiled, or treated with ammonia, appears of a grey tint by transmitted light.

By an exposure of two minutes to the band of coloured light, obtained by passing a beam of white light through a spectroscopic, Abney obtained coloured pictures of the solar spectrum upon silver (Daguerreotype) plates and upon collodion films. He considered the colours obtained to be due to the mixture, upon the same plate, of the first two modifications of the silver bromide molecule described above, the first absorbing the light of the blue and the second that of the red end of the spectrum.

But still the original problem confronts and baffles us. No means are known of giving permanence to the size or form of these colour-producing molecules; indeed, the molecules themselves are decomposed, or radically altered, by the ordinary "fixing" agents employed by the photographer.

Under the influence of white light the coloured molecules of silver bromide also change; they are decomposed and the colours disappear. And after all, the colours which we have as yet been able to obtain, but not to fix, by means of photography, are but faint and dim, poor reflections of the brilliant tints of nature.

In this work of obtaining naturally coloured photographs there is clearly a fine field for experiment and research. How many photographers have attempted even to confirm the results obtained by Becquerel, Niepce, and Abney? And yet what an interesting and important task this would be. The references given in this paper will enable any one who has access to a good library, such as our leading photographic societies ought each to possess, to ascertain the details of working. It is my intention to attempt something in this direction during the coming "sun season," and I should be pleased to co-operate with other chemists and physicists interested in the problem, in which case the whole ground might perhaps be gone over.

W. JEROME HARRISON, F.G.S.

ACCESSORIES OF THE LANTERN.

CHAPTER VI.—THE LECTURER'S READING DESK.

THE distance meter, described on page 215, which is used for ascertaining the right place to fix the lantern so that the image on the screen shall be of the desired dimensions, does not pretend to mathematical correctness. There is a very small difference between its indications and the theoretical positions, a difference not greater than might be produced by the overstretching of a long tape measure. The error is so trifling that it is quite unnecessary to make any allowance or correction for it in ordinary lantern exhibitions, as we are not obliged to have our pictures of any special size. As an example, we will suppose the distance meter is used for a lantern fitted with front lenses of seven inches equivalent focus, the adjustment being made on a twelve feet disc. If the meter is now used to find the correct position of the lantern for a ten feet disc the distance so found will be one inch too short; and if the lantern was accurately placed according to the meter to give a picture five, six, or eight feet in diameter, the image would be one and a quarter inches smaller than that calculated for. With discs larger than twelve feet the error would be a surplus one; in the case of a twenty feet disc the image would be one and a half inches too large. Such differences are too small to be readily detected in practice, and our simple distance meter may safely be regarded as a perfectly reliable accessory.

The illuminated reading desk is indispensable to most amateur lantern lecturers, and is of great service to professional speakers. The latter class often know their lectures so well by frequent repetition, that they are able to dispense entirely with written notes, and they find that such speaking is more effective than the reading of manuscript. There are, however, occasions when a reference to statistics, names of places, and the like, becomes necessary, and then the desk is found useful, although not needed during the whole of the discourse.

Turning to amateur or occasional speakers, we find reading to be the rule rather than the exception. Printed lectures on a variety of subjects are obtainable from the opticians, and these are in consider-

able demand, being almost invariably wanted when a set of slides is hired or purchased. As few people are born elocutionists, or have devoted special study to the art of reading aloud, the delivery of these printed lectures is usually productive of drowsiness among the audience, especially if the reader has not previously perused his piece, and is too nervous to understand it, when he is reading it before an assembly.

To be successful as a lecturer, it is necessary for the speaker to have a thorough mental grasp and comprehension of his subject, and to feel a strong personal interest in it, in order to arouse similar interest and comprehension in his audience. If he reads a joke and fails to see the point of it himself it is nine chances out of ten that the audience will also miss it. If he reads through a printed lecture, and at the end is unable to remember what he has been saying, he may be very sure that most of his listeners will go home in similar blissful ignorance. Amateur lecturers are often effective, but it is only when they are speaking from their own previously acquired knowledge of the subject which is described in their own words. If their language is not so choice and their style is not so dignified as the printed matter, their discourse is far more intelligible and interesting to the listener.

Those who are in the habit of hiring slides, and getting the descriptive information from the pamphlets supplied with them, will generally succeed best by making themselves familiar with the main features of the lecture, and writing brief notes of the names of persons, places, and statistics. Then let them rely upon their own command of language to describe the views, referring to the notes for such details as are not easily retained in the memory.

The position usually occupied by the lantern lecturer is at the side of the picture, just out of reach of the cone of rays thrown by the lantern. He is himself in semi-obscure, though he can see his audience by the light reflected from the sheet if the disc is properly illuminated. If he wishes to be seen, in order to better illustrate his meaning by gesture or expression, he stands in front of the screen, and instantly loses sight of everything save the dazzling bull's-eye of the lantern. The audience can see him but he cannot see them. He should place himself in front of the picture at a part where there are no small details. If the audience saw his features decorated with a lamp-post on the one cheek, and a donkey's head on the other, or some similar objects included in the picture then being exhibited, they would not be able to appreciate the finer shades of expression so well as if his face was unadorned in this way.

The most original idea in connection with the lecturer's position that I have met with is to use a magnified Punch and Judy stand, with an inclined plate-glass mirror therein. The mirror is perforated in the centre with a hole sufficiently large to admit of the head of the performer being passed through as far as the neck. The appearance is then that of the "floating cherub" illusion, a living head without a body suspended in space. I have never seen a lecturer deprived of his body in this manner, but I have no doubt such an apparatus would be very useful to a speaker who had more confidence in the beauty of his headpiece viewed by itself than in the appearance of his bodily framework as a whole.

A reading desk should be of simple construction, so that it can be put up in a very short time. It should be light, and should pack into a small compass for convenience of travelling. The illuminant, whether candle or lamp, should not drop grease or oil, and should not require any special care and attention. The light should fall only on the desk, no ray escaping in any other direction. The covering of the light should be small, so as not to hide the speaker and intercept his voice, and there should be means of signalling to the operator at the lantern both by the bell and by the flash of red light.

The desk may be a thin mahogany board, ten inches long and eight wide. A strip of wood is fixed on one edge to prevent the book slipping off when the board is held in the inclined position. The board should have some appliance to raise it ten or twelve inches above the table it is placed upon. This can be done by means of four laths, which are jointed to make a couple of X's. These are fitted up on the principle of the folding camp stool, with four legs and canvas seat, sold by artists' dealers. The top of our miniature camp stool is made sloping instead of being horizontal, so that the desk board, being hinged to the raised part of the canvas "seat," will rest

securely thereon at a proper angle for the reader. To pack this apparatus the jointed legs of the X's are brought together into a line with each other; they will then fold flat on the desk, and the whole can be easily put in the lantern or slide box. A strip of cretonne, or ornamental cloth, may be buttoned on three sides of the desk to conceal the stand from the view of the audience, and to impart a more showy appearance.

Another way of supporting the desk is to dispense with the table, and to mount the board on the top of a short pole or broomstick. The lower end of the pole is fitted with a projecting screw, which is inserted in the floor boards; the pole is jointed in the middle, on the fishing rod principle, for convenience of packing, and the foot is fitted with a tin cone, with a base three inches in diameter to lessen the strain on the screw. This stand is a little shaky, and after it is fixed up anywhere it is a troublesome matter to alter its position; and as every hall is provided with a small table for the platform, the table reading desk is, on the whole, preferable to the pole stand.

A tourist's folding tripod is sometimes employed as a stand for the desk; it answers fairly well, being of a proper height for reading. It does not look quite so dignified as the more substantial table, and if the lecturer happens to get excited with his discourse, and accidentally touches the desk with his waving arm, it may be knocked off the platform, and sent on a visit to the audience; or if in the obscurity he catches his foot on one of the invisible tripod legs, the whole concern may descend swiftly to the floor (as I have seen). And if by this accident something breaks, and the lamp cannot immediately be relit, the lecturer may be reduced to reading his piece by the light of a dripping tallow candle held in his left hand, while he brandishes the pointer in his right (as I have also seen). Under such circumstances the dignity and equanimity of the lecturer are jeopardised, and unless the tripod legs are screwed to the floor the plan cannot be strongly recommended.

ALBERT WM. SCOTT.

NOTES FROM AMERICA.

THE EXHIBITION OF PHOTOGRAPHS.—The first annual exhibition of photographs, comprising the work of the Photographic Society of Philadelphia, the Boston Camera Club, the Society of Amateur Photographers of New York, and many other American and foreign amateur and professional photographers, was auspiciously opened on the evening of March 26 by a well attended "private view" to members, exhibitors, and "the Press." The exhibition remained open day and evening until April 2, with lantern slide exhibitions on Monday, Wednesday, and Friday evenings. There were about eleven hundred prints exhibited in nearly four hundred frames by over ninety exhibitors. England was creditably represented by ten exhibitors; Boston, by seventeen; Philadelphia, by nineteen; New York, by thirty-eight; Austria and Prussia, by one each; while the remaining photographs were sent from various parts of the United States. Several ladies had the distinction of exhibiting some of the best work that was shown. The exhibition was varied by prints of many processes. Platinotypes, bromide, and carbon prints; cyanotypes and the usual silver prints were well represented. Besides one hundred and twenty-three lantern slides, there were twelve transparencies, which added much to the interest of the exhibition. The exhibition was in every way a complete success, and reflects much credit upon the Committee of Arrangements. One feature which showed especially considerable enterprise on the part of the managers was the catalogue giving names and numbers of prints, and the particulars concerning development and printing. This will prove a valuable *souvenir* of the exhibition. All the prints were framed, and for the most part carefully; and they were arranged so as to form more or less sharply defined panels on the walls, which gave a pleasing effect to the exhibition as a whole.

THE STEWART COLLECTION.—It was pleasant to notice the prominent part which photography played in a recent notable sale of art treasures. The famous Stewart collection of paintings—which was lately sold at auction in this country, and which excited so much interest here, outside of art circles even, that I doubt not many readers of the JOURNAL have heard of the sale on their side of the water ere this—was the subject of an illustrated catalogue *de luxe*, limited to 500 copies, containing photogravure reproductions by Mr. Ernest Edward's beautiful process of the more notable of these pictures. Some of the photogravures were made from negatives by Mr. W. Kurtz, of this city, which he exposed on the paintings under his electric lights; others were from negatives on orthochromatic

plates, and these showed very fine gradation of the colour shades. The catalogue is itself an art treasure, worthy of the famous paintings therein reproduced and of photography.

New York.

W. J. LINCOLN ADAMS.

THE PRESERVATION OF ASTRONOMICAL PHOTOGRAPHS.

IN the future, photography will be so intimately connected with astronomical research, that the permanence of the records produced by the graphical utilisation of luminous rays becomes a question of vital moment, the more particularly because in not a few cases the chief value of the photographs should consist in their giving the power of comparison with photographs of the same celestial objects taken some centuries later.

The platinum photographic process, which is probably the most permanent of all those upon paper, is inadmissible in astronomy for all purposes in which questions of exact measurement are concerned, because of the irregularities of the surface of the material and the variations in the size of the sheet with changing hygroscopic conditions. Moreover, in the act of printing from any negative, even upon the most perfect film below it, there is always some risk of the introduction of small dimensional errors, hence attention must be chiefly concentrated upon methods of making the original negatives, taken direct from the stars themselves, as nearly as possible imperishable.

A present-day negative upon a gelatine film, when coated with a good varnish, and afterwards stored under the best conditions for preservation, is known to possess a considerable degree of permanency, especially if three points have received attention, namely:—(1), That the thiosulphate of soda has been thoroughly washed out of the film; (2), that in the latter part of the manipulations the film has been subjected to the hardening influence of an alum bath; (3), that it was thoroughly dry at the time of varnishing. The perishability of coatings of varnish is, however, a matter of common experience in everyday life, and upon carefully stored negatives coated with superior varnishes, the same deteriorating influences must produce in a long time the same effects which they do in other cases in a short time. No resinous varnish seems to be damp proof. A rough-and-ready way to test the water-resisting powers of different varnishes is simply to coat useless negatives with them and to place them under water; in more or less time star-like markings make their appearance. In relation to durability, other conditions have also to be taken into consideration, such, for instance, as the tendency of some varnishes to crack and even split off with age, as with amber.

These facts suggest the idea that either varnish must not be used or that if used it must itself be protected, which principles lead us up to one of the earliest methods employed for the preservation of astronomical photographs. More than twenty years ago, when Mr. Warren De la Rue was taking photographs of the moon at his observatory at Cranford, he showed me how he rendered them to some extent durable by cementing a piece of glass over each negative with Canada balsam. The photographs were taken upon circular pieces of patent plate-glass, two and three-quarter inches in diameter; the smaller circular pieces of glass subsequently cemented upon these were two and a quarter inches in diameter. A flat plate of brass was first adjusted in a truly horizontal position by means of a circular spirit level, then it was heated, with the negative upon it, by means of small gas flames underneath; the second and smaller plate of glass, also warmed, was next laid face downwards upon the photograph, but touched it only at one part of its circumference, because a strip of paper was placed beneath the opposite part of the upper disc. A few drops of Canada balsam were then allowed to fall upon the lower plate where the upper one touched it, opposite the strip of paper; the warm balsam then by capillary attraction slowly travelled between the two plates, and when it had two-thirds occupied the space between them, the slip of paper was removed, the balsam continued to travel, and in about fifteen minutes from the commencement of the operation the union of the two glasses by balsam was complete. The object of applying the balsam in this way was to get rid of air-bubbles. For the same reason, the "feeding" of the superimposed glasses must begin only at one spot; if it be attempted to quicken operations by means of two starting points, there is danger of the two slow waves travelling between the glasses taking such a form as to enclose a bubble of air.

John Quekett, in his *Practical Treatise on the Microscope*, 1852, states that Canada balsam is not good for the cementation of microscopic slides, because after the lapse of a few years it becomes brittle, and then the slightest jar or bending will cause the glasses to split apart. He recommends marine glue as a better material for the

purpose. When the duration of the material for centuries is in question, the use of a substance so rich in indiarubber seems to be undesirable, for caoutchouc is acted upon both by air and light. Sometimes arborescent appearances form between cemented photographic lenses, due probably to the Canada balsam used as the cement having been artificially, or naturally, diluted with too much volatile oil. Mr. John Browning once told me that these arborescent markings depend upon the sample of Canada balsam used, and that if he obtains such a sample he throws it away; he states that old specimens of the balsam are most free from the defect, and that for cementing lenses he always selects as old a sample as possible.

In the years 1867-68, I had been considering the various points mentioned in this communication, and at the suggestion of an acquaintance began by getting rid of most of the volatile oil in Canada balsam by keeping it at a warm temperature for a long time. The next point was to remove its tendency to brittleness by the addition of a small proportion of castor oil, which varnish makers know to be about the best material for "toughening" varnishes, that is to say, for preventing their cracking. Thus a heavy and stable oil is substituted for the natural volatile oil in Canada balsam. Castor oil occupies a position half-way between the drying and non-drying oils; a thin film of it left exposed for an excessively long time to air will at last dry into a skin. Photographs when printed as transparencies upon glass yield fine details, which they lose when printed upon paper, so I wrote to two photographers who possessed negative portraits of Professors Faraday and Tyndall, and purchased unvarnished collodion positives printed therefrom as transparencies upon patent plate-glass. With heat I cemented with Canada balsam and castor oil a piece of patent plate-glass over the portrait films, which have since been preserved like flies in amber, and probably are the most complete and permanent portraits of those philosophers now in existence. A few days ago, after the lapse of nineteen years, I examined those transparencies; there was no perceptible change in them, indeed, none was to be expected, because many carefully kept varnished, ordinary collodion negatives will show no change after the lapse of a quarter of a century. The most interesting point was, however, that in my transparencies where the cement had been from the first squeezed out at the edges of the plates, consequently was there freely exposed to atmospheric influences, it is now not brittle but somewhat flexible and soft.

The point to be attained in the protection of astronomical photographs is, I think, to make them as imperishable in their glass and hydrocarbon coverings as the now extinct tropical hymenoptera, diptera, and other insects, which in prehistoric ages were imprisoned and preserved in the drops of gum falling from the amber trees upon the shores of the Baltic. The solution of the problem will probably be found in the use of a stable resin, such, perhaps, as amber itself, toughened with castor oil, or, perhaps, with a non-drying oil. The knowledge of the amount of permanence of any present-day astronomical photographs must necessarily be hypothetical in its nature, and he would render good service to science who would cement together a sufficient quantity of glasses by carefully recorded substances and methods, and put them under the care of some permanent scientific institution, which he should authorise to examine and report upon one batch out of the collection at the end of every century. Meanwhile, the safest plan will be to take several negatives of the same stellar objects at the same time, and trust to astronomers of the future, when symptoms of decay occur in some of the photographs, to take accurate copies of the remainder.

W. H. HARRISON.

MECHANICAL OPTICAL LANTERNS.

II.

DISSOLVING view apparatus, although generally associated with two or more lanterns forming a pair or a triple lantern, with precisely similar optical systems, also include those single optical lanterns that have mechanical means for dissolving and changing the slides. In this class are lanterns fitted with Rudge's or Edwards's dissolving carrier, or Rudge's quick-changing shutter carrier, Davenport's vertical curtain screen and carrier, and the Presto dissolving carrier.

In the first two the photographs or pictures are placed in a frame sliding horizontally in a carrier fixed in the lantern, which is moved backward and forward by turning a handle acting on a cam and rack-work, or by bands and pulleys, and allows of any number being shown in turn, the same handle acting on levers and arms, to which are attached fans or discs in front of the objective lens (or on the shutters immediately over the photograph) which gradually covers up the slide last projected on the screen, then changes it and uncovers the next.

With Mr. Davenport's curtain carrier, as fitted to the Society of Arts' electric lantern, provision is made for the insertion of the slides underneath the stage, and therefore the lantern must have no projecting footboard as usually fitted, and if of the ordinary size body it must be raised about eight inches in order that a long frame may pass vertically through the stage. By an ingeniously contrived slide moving in the frame, each photograph or view after being temporarily dropped in a wooden holder can be pushed up into position and held there by a simple spring stop. The act of pushing the holder up carries with it a metal screen, cut out to such a shape as shall as nearly as possible correspond with side curtains, gradually widening from bottom to top, and finally becoming the width of the picture. As everything is reversed on the screen, it has the effect to the audience of a black curtain coming down and shutting out the picture until it is quite obscured. When this takes place the next photograph is in position in the lantern, and the previous one has been pushed up higher, so that it can be withdrawn from the top of the lantern stage. The act of drawing down the slider brings down the metal curtain (up on the screen), and a new slide holder can then be inserted. Although an excellent arrangement, no doubt, for moderately lighted single lanterns, I question it being the best form of blind or changing arrangement for an electric light lantern; for where the light is so intense on the screen, the very great change from total darkness to abnormal brilliancy is too much for the greater number of eyesights to bear comfortably, and in my opinion calculated to create a severe strain on the eye by the constantly recurring changes necessitating such a rapid contraction and expansion of the iris or diaphragm of the eye. I certainly can speak for myself when at the exhibition given at the South London Photographic Society's meeting, the pictures following each other in rapid succession on account of the number to be shown and the small amount of description necessary to each, my eyes quite ached before half the slides had been gone through. As I am accustomed to look at strong lights, and my eyes are fairly trained by testing optical instruments and experimental work to stand average strain, I think it is fair to assume that others must have found it trying. Probably the reason why some consider that the Society of Arts' lantern gives too intense a light, is due to the great contrasts alluded to; but if dissolved by means of grey or ground glasses, talc or coloured glasses, a softening effect would have been produced on the eyesight not possible with a metal or opaque curtain shaped screen.

The Presto dissolving carriers are modifications of Rudge's and Edwards's.

With these mechanical changing and dissolving carriers the operator has only to be careful to put the photograph in the right way up and proper side to light, and repeat the operation of either turning a handle or sliding the frame after inserting a fresh photograph, and then taking out the last one shown.

I know of no way in which "effects" can be shown perfectly by an unskilled operator, for they require a great amount of centering and adjusting as a preliminary, and very careful insertion into the lanterns at the time of exhibition; but much has been done by putting special adjustments to the better class of dissolving view lanterns recently made, to render it possible after once setting the pictures and effects accurately in their frames, and registering them to the lantern, to place the slides in either stage at any distance from the screen and be sure of the effect appearing in exactly the right position on the set picture, supposing the lantern stages are adjusted at that position so that the standard set of slides or registering crosses are made to coincide before starting the entertainment. As long, however, as effects are not wanted, a perfect mechanical dissolving lantern is possible, for Mr. Duncan designed and had constructed for himself a very unique piece of apparatus, that by means of two pedals worked by the feet was capable of changing the slide in either lantern and raising or lowering the lights at will so as to produce the orthodox dissolving by limelight. It was so cleverly conceived that I cannot but think a description of it will be interesting.

The lantern proper consisted of one of J. H. Steward's Bridgman triple lanterns, made specially strong, and slightly different to usual, namely, in three parts one above the other and the cut sections hinged so as to incline bodily to get superposition on screen, and not as usual by the front alone—the open part of body when inclined being covered by an ornamental moulding. To the bottom and middle lantern was attached the machinery for moving the slides or photographs through the lantern stage and apparatus for mechanically dissolving the pictures. On each side of the body are fixed two pairs of steel rectangular bars set with their edges upwards like a diamond, and on these travel a partitioned box something like the ordinary racked box to contain lantern slides, or a plate box, without one of its sides, and each held thirty-six $3\frac{1}{4} \times 3\frac{1}{4}$ photographs, therefore if all

were full it could contain one hundred and forty-four slides; as, however, the boxes on one side of lantern must be empty there are available at starting seventy-two slides. These boxes are connected together by stays and guides, and a plunger on the one side acts against the edges of the slides in the full box, and, on being actuated by the levers and pedals to which they are attached, moves the slide forward its own length (three and a quarter inches). The result of this is that the slide set in the stage, so as to show on the screen when the lantern is uncovered, is moved forward, and the dummy that helps to fill up the intervening space between the lantern body and the empty rack box is pushed into the first vacant groove. The reverse stroke of the pedal moves the groove boxes forward on the bar, a distance equal to the amount the photographs are separated, and a connecting lever lowers the light in one lantern and raises it in the other, and produces by so doing the dissolving effect. In this apparatus the top lantern was fitted with an ordinary stage for effects, and with a curtain shutter for rolling up effects; but, practically, the designer relied on the mechanical arrangement for showing the photographs and views, simply working the pedals with his feet while reading the lecture or giving a description. If a larger number than seventy-two photographs were required, other racked boxes could be inserted in place of those used up.

G. R. BAKER.

WHERE I WENT WITH THE CAMERA.

NO. III.—TO ARNHEIM AND VELP.

On leaving Rotterdam I took train for Arnheim, and as we jogged along—for even an “express” is a very leisurely affair here—I came to the conclusion that Holland was a country of a pattern peculiarly its own. Its scenes, its people, and its habits, all original and belonging to itself—a monopoly—and not resembling any other country I had ever seen or read about. Its landscapes lack hill and dale, yet they are picturesque in the extreme. Its people are slow, and kind, and obliging; never in a hurry, yet always moving on; with quaint manners and peculiar dress, which has that fascination for the stranger belonging to all things new.

There was water everywhere. As we pass through the country every little advance brings to view canals running down through the fields, repeating themselves at intervals regularly as lines in a copybook, and on the patches of land between were built the farmhouses, in many cases sheltered by trees, which I found grew more luxuriantly as we proceeded further into the interior of the country. Along the sides of the railway line were broad ditches or canals cut, which must be very seldom used, for a green weed covers the surface of the water completely, and the only time the water is seen is when we come across a part where some voyager has had to travel through it, thus leaving the track of his boat visibly marked. On the patches of land there were gates fitted up on each, and at the gates on every patch were the cows congregated, patiently waiting, for it was milking-time, and they knew it.

The husbandman and his wife could be seen in the distance trudging along in their leisurely way to milk the cows, carrying a pail at either side hung from a bar placed across the shoulders, and others who had already arrived were busy milking. “This land is so damp and watery,” exclaimed a friend, “that the very cows have to wear waterproofs.” And that is so. The cows in Holland wear waterproofs. And another feature about them that strikes the stranger, they are all black and white. Amongst hundreds of cattle only two or three brown or red would be seen.

As we get along the trees improve in size and foliage. Willows, the most stunted and unpicturesque of all, grow in great quantities; but this is, I suppose, for a commercial purpose, the twigs being largely used for wickerwork and basket making.

Arnheim was a fine old town when the Rhine that flows past it was a few hundreds of years younger, and for centuries it held its own against encroachment; but the walls and the moats have passed away and “a change has come over the spirit of its dream.” In the course of twenty years it has doubled its inhabitants, and it has now the credit of being a pretty, elegant, and wealthy city. Most parts of it strike one as modern, and in the march of the newer fashion the beauty and interest of bygone days is being quietly brushed out into the nothingness of the past, although away down by the landing-stage on the Rhine one could still feel the full atmosphere of Holland all around. Amongst some of the oldest buildings in the city still left is the Town Hall, or Devil’s House, as it is sometimes called on account of the grotesque carvings that adorn it, and the Cathedral, some four hundred years old. After securing various pictures of the town, new and old, I thought that I would like to get a general view of the city from the steeple of the Cathedral, and although the day was rather windy I ventured it. You all know what those steeples are. I mount five hundred steps—half-way to the sky—up at last amongst the hanging ropes and pulleys, gasping for breath and sitting down waiting till it comes, gazing up amongst the brazen bells and wondering which amongst them would be nearest in size to that Quasimodo rode and swung and made night hideous with its clash and clang. At length I gain my breath, and leaving off dreaming come down to work again. When I got out on the terrace built round the spire the wind was howling wildly—still I managed to get one picture; but when focussing for

the second one over blew my camera, which I caught just in the nick of time, but as I was in the act, right out of my hand was the focussing cloth blown over the houses and far away. I felt that I had experienced enough rough usage for one day, so I packed up my traps and descended to the level of ordinary mortals.

The walk from Arnheim to Velp, a distance of some four English miles, is very brilliant and full of interest; the trees in this part of the country are profuse and the foliage most luxuriant—a new feature of the country this for me. Beautiful avenues extend for miles and miles all around this district; beech, oak, chestnut, and linden, are all found here in profusion. Villas and mansion-houses of every varied style of architecture adorn the Velp highway, all looking in the sunshine bright and new, as if just painted that morning. Not one of them but would furnish a charming study, as each and all peer out from their nests of foliage which surround them, no matter how near the road they stand, with their airy, flowery terraces and cool verandahs bursting with blossoms dancing in the sun, whilst rustic tables, chairs, and lounges, are strewn about the lawns and grounds, all telling the story of that good time when the “pile” is made, and the world’s toil is over.

About two miles down the Velp road to the right, I came upon a large and beautiful house standing on an eminence and surrounded by its own grounds, which embraced many acres. I entered the gate and made my way up to this imposing edifice, which was all decked with flags. I found that it was called Planten-en-Voyluint, and one could stay there as long as he liked—to pay, for it was a hotel combined with pleasure grounds. For a day’s enjoyment a better place could not be found. It is the resort—on Sundays especially—of the “upper ten” of Arnheim. Bands of music are then provided, and hundreds from the city gather in these grounds, which have been appointed and arranged with every inducement and care for the visitor’s pleasure and enjoyment. There are hot-houses with all kinds of exotic plants; birds and fowls on view, of every kind from every country; water fountains playing in the summer, and lakes lying ready waiting for John Frost to touch them with his wintery wand to make them ready for the skaters. Fancy dress balls are got up for the youngsters, and concerts for the oldsters, with other appropriate pleasures turning up all the year round. Verily, they know how to enjoy themselves.

On the other side of the way and nearer Velp, I reached a place of considerable interest, Bronheek, a country seat that was, in 1854, bought by King William III., and presented to the country to be used as a home for the soldiers who had served in India. The corridors are hung with arms, and spoils from afar decorate the walls. The inmates of this healthy and beautiful home keep all the grounds in order themselves. They have laid aside the sword and taken to the pruning hook, the glory of war is forgotten in the rearing of roses. And like Goodale’s “career”—

“What does he do?” He prunes his roses

Near Arnheim, at a villa there;

’Neath soft Holland skies he closes

The book of life: without a care,

He smiles and takes his ease.

* * * * *

An ardent boy—he dreamed of Honour

And Fame—his heart was set upon her!

* * * * *

‘What has he done?’ He prunes his roses

And quite content, the book he closes.”

I hear the tinkling of the tram bell, and so must move along. On reaching Velp I found a village embedded in foliage, out of which I got a few good photographic studies. This place was passing rich in restaurants, with heaps of tables and chairs scattered all over the place outside, as if they were going to have a sale of second-hand furniture.

From Velp I journeyed on to the village of Rheden. MARK OUTE.

Department for Inexperienced Photographers.

SKIES AND CLOUDS.

If one examines a fine landscape having a plain white sky, devoid of either gradation or a semblance of clouds, and then turns to a duplicate print in which there is a sky covered in whole or part with clouds of beautiful form, the difference between these two in point of artistic merit will be immediately appreciable.

Photographers who prepare their pictures for exhibitions are so well aware of this, that in most cases they bestow great pains upon their skies, some of them overdoing it to the extent of reversing what ought to be the correct position of things and making the landscape subordinate to the sky, while others are guilty of the bad taste of printing in one set of clouds on every picture. We have seen in one of our public London Exhibitions a row of landscapes by a photographer of repute, all of them beautiful, but each possessing the same individual sky as its fellow. This is not seemly.

One cannot always get a fine sky when he or she arrives at a particular place and finds the scene lighted up for photographing as if “to order.”

Things terrestrial must claim immediate attention, and the sky be left out in the cold.

We shall assume that a landscape negative has eventually been secured in which every artistic and technical condition has been fulfilled. But the sky; it is a plain dark grey, and detracts from the effect. What is to be done?

If the horizon of the subject be of such a nature as to render it easy to stop out the sky altogether, this might be done. China ink and a finely pointed camel's hair pencil provide the means. It is not necessary that much more than a mere outline to the horizon be thus applied, because the mass of the sky may be blocked out by covering it on the back of the negative with opaque paper pasted on the glass, or by black varnish applied by broad sweeps of the brush. A very good way is to make a print from the negative, cut out the sky portion with a knife or scissors, allow it to continue to darken in the light, and affix this to the negative as a mask.

The result of all this is that we have obtained a well-printed landscape having an unmeaning plain white sky. A simple way of imparting an even graduated tone to the sky consists in laying the print face up on any rigid board—a cover of a book will answer—then placing upon it a plate of glass so as to keep it flat, and placing over all a sheet of card or brown paper. Now step out into a good light and expose the sky to light by slowly pulling down the brown paper cover from the top of the picture to the horizon line. If this be done steadily a beautifully graduated sky will result, one in which the top is darkest, as it usually is in Nature, lightening by imperceptible degrees until the horizon is reached, which is left nearly white. This makes a very useful and even pretty sky.

If the photographer be very skilful with the brush we could recommend him, instead of blocking out the sky, to paint on it such clouds as the nature of the subject might demand. A safer way is to have a series of cloud negatives, which may be taken at leisure and retained in stock. These negatives may either be made on glass or paper.

It will conduce greatly to the beauty of a sky if, while it is being printed in from a cloud negative, the method of grading already described be employed.

Clouds can be readily made on the back of a negative by pasting over it a sheet of thin tissue-paper, and working on it with a soft plumbago pencil or a crayon stump. Some even go the length of grinding the back of the negative with emery and water in order to ensure a tooth for the pencil touches. Ground-glass varnish will answer the same purpose, provided it be hard enough to stand the friction of the pencil.

A way we have often adopted with advantage is to make a sky negative on a collodion plate, strip the film off, and attach it to the landscape negative.

If the photographer is so happily situated as to secure a good sky in the landscape negative this is, of course, best of all; but it often happens that such cannot be done, and hence the necessity of such expedients as the subsequent printing-in of clouds.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at the ordinary weekly meeting of the above Society, held at 5A, Pall Mall East, London, Mr. James Glaisher, F.R.S., President, occupied the chair.

Mr. J. CADETT read a paper upon *Standard Diaphragms for Lenses*, in which he said that in the standard fixed by the Society the focal length divided by four had been chosen as the unit from which to start, but that quite recently Mr. Dallmeyer had suggested that a better unit might be adopted. According to Mr. Dallmeyer's plan, ten would be the divisor of the squares of the denominators instead of sixteen in calculating the relative exposures; with small apertures this would give least trouble in calculation, but with large apertures there would not be much to choose between the two systems; by his system it was merely necessary to insert a decimal point, whereas by the Society's system it was necessary to do a sum in division. As the Society wanted all other photographic associations to accept its standard, he thought it to be better to use a decimal system of notation, especially as it was more likely then to be acceptable on the Continent. There was only one case in which division by the square root of ten, that is to say, by 3.162, would be necessary, and that was his answer to Mr. Debenham's objection on this point.

Mr. W. E. DEBENHAM premised that a standard that has the authority of the Society's recommendation, and that has been adopted in consequence, should not be altered, except for weighty reasons or manifest superiority in the one proposed to take its place. There being three distinct cases in which the use of the standards may be compared, it would be well to see which case was of the most importance as requiring ease and simplicity of calculation, and compare the accepted and proposed standards with respect to each case. The case of first importance was that of the use in the studio or field of lenses or stops which have been previously marked with a number in relation to the standard. This is of first importance because of constant occurrence, whereas the marking should be done by the optician or photographer himself at home, and once for all. In this case, the only difference favours the accepted standard, the proposed standard requiring numbers about half as large again as those at present in use. This practical advantage of the present standard, he said, had been admitted by Mr. Dallmeyer, who, however, considers it but a small one. Nevertheless, the only objection of any weight that has been made against the Society's standard is that the numbers are, when using small apertures, already high. The second case for consideration was that of forming a set of apertures of sizes to bear simple numbers in relation to the standard in use. To do this, it became necessary to first obtain a dimension representing the standard aperture, and then divide this aperture as required for the smaller openings. The Society's standard aperture is obtained by dividing the focal length by four; with the proposed standard the division is the root of ten, or 3.162, &c. It was obvious that in this case of obtaining the sizes for standardised diaphragms the present standard was far more convenient than the proposed one. The third case was that of comparing apertures that have not been cut to any standard, and numbering them in accordance with the standard. This was a case which might be expected to become more and more rare, and eventually die out, as diaphragms are cut to bear a simple relation to the standard in use. Indeed, it was worth while, on account of simplicity of calculation, to have diaphragms recent where need be, so as to enjoy that simplicity. When irregular openings have to be compared there are two methods of doing it. The method considered the simplest and easiest in most cases for those who are not opticians or mathematicians is the graphic method, and for this method a unit has to be obtained, as before, by dividing the focal length by four for the Society unit, or 3.162, &c., for the proposed one. If, however, the arithmetical method be adopted, the focal length must, for either standard, be divided by the aperture, and, with unregulated opening, both divisor and dividend will probably include several decimals. The quotient must then be squared, and where the number is high all this is such a lengthy operation that subsequent division by ten or sixteen is comparatively trifling; and, in concluding, Mr. Debenham submitted that any advantage presented by the proposed standard was far outweighed by its disadvantages in the other cases referred to.

Mr. J. R. GOTZ believed the present system to answer well, because it brought to the eye of every photographer a simple reading of the relative exposures, and he hoped the Society would adhere to its present standard, which was doing good general service. He, or rather the firm which he represented, had been the first to carry out its standards right through, and before long people would not accept any lens except upon those standards; the lenses of other makers were sometimes sent to him to have the diaphragms cut to the standards of the Society. More lenses are imported, made, and used in this country than anywhere on the Continent, and perhaps than in the whole world put together, so the Society need not trouble about the decimal system; the simple plan of giving each nearest exposure twice that of the one before answered well.

Mr. T. BOLAS said that Mr. Gotz's remarks would apply as well to any other system as to that of the standards of the Society, but the main point was to get a standard which should be most acceptable to the world at large, which would consist chiefly of foreigners. The Society might do well to invite opinions upon the subject from all the leading Continental societies, opticians, and users of lenses.

Mr. S. G. B. WOLLASTON remarked that the standard had been adopted but a short time, yet a large number of foreign opticians were already making lenses in accordance therewith and sending them to this country; perhaps those foreign makers would not adopt a fresh standard. Many lenses passed through his hands in the course of the year to test and report upon, and there was a prevalent desire that they should agree with the present standard. He thought that no material alterations should be made at present.

Mr. G. L. ADDENBROOKE said that by Mr. Dallmeyer's plan the smaller stops of landscape lenses would run into very high numbers, and then the user could not get mentally at their relative values so easily as at present in the field.

Mr. W. BRIDFORD stated that the Committee of the Society which framed the standard wished it to be adopted in its entirety; had that been done by the leading opticians he did not think that any necessity would have been felt for revision. The fact that the system had been largely adopted should weigh with the Society before making any changes.

Mr. DALLMEYER said that Mr. Debenham had objected to the height of his numbers of comparison, but when the numbers became small in relation to the rapidity of the lenses, the difference became trifling. When, however, numbers of three figures were reached in the field, the stated difficulty could be

overcome by shifting the decimal point one figure higher up. Mr. Debenham's objection to the construction of the stops would apply only in one instance. It was to be regretted that the decimal standard had not been adopted before; it was simple, and the real point at issue was only as to a question of precedent. He suggested that if it were granted that there were advantages in his system, a Committee might be formed to consider it, and to see if opticians were willing to carry it out. If a Committee were to investigate, it might find that his plan could be simplified. His father had been unable to attend the meetings of the previous Committee because of ill-health.

Mr. DEBENHAM argued that Mr. Dallmeyer's simplifications were more apparent than real.

Mr. CADETT stated that both systems required the square root to be extracted, after which Mr. Dallmeyer's system became the easier. Such questions should be considered on their merits, and a particular plan not adhered to merely because it was old.

The PRESIDENT remarked that the Committee which had recommended the present standards consisted of Messrs. Warnerke, Abney, Davis, Darwin, Dallmeyer, Belford, Brownrigg, England, Cowan, Stuart, Heaviside, and Wortley. Of these Mr. Heaviside and the late Mr. Dallmeyer had not attended any of the meetings. The Society was grateful for any fresh information on the subject, and the question was whether the Committee should be reappointed. At the meeting of the Society next Tuesday night the subject would be *Stripping Films*.

Colonel R. Malden and Mr. John R. Gotz were elected members of the Society, and the proceedings closed.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, April 14, at a meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. W. E. Debenham presided.

Mr. J. TRAILL TAYLOR said, in relation to a question put at the previous meeting, that an American professor had showed him his apparatus for making oxygen near the optical lantern as fast as the jet of the latter used it up; the apparatus worked well, and at a future time he would give a description of it to the Association.

Mr. A. L. HENDERSON exhibited instantaneous photographs he had taken of the demonstration in Hyde Park on Easter Monday against the Irish Coercion Bill; he used a stand about ten feet high and reached the camera by means of a step ladder.

The CHAIRMAN remarked that, as no halation appeared in the prints where the contrasts were strong, he presumed that Mr. Henderson had used plates thickly coated with emulsion, and probably not commercial plates.

Mr. H. M. Smith exhibited a photograph which had come out tolerably well, although by accident he had placed the wrong side of the plate in the focal plane.

Mr. L. Medland exhibited some views of Maidenhead.

A question in the box asked what was the best lens for a detective camera.

Mr. TAYLOR said that for a dark day and where extreme rapidity was required a small portrait lens without a stop was the best; the next most rapid was a doublet worked at about $\frac{f}{2}$ or $\frac{f}{2.2}$, and of as short a focus as possible, to obviate the necessity for focussing. A lens of about five or six inches focal length would be found to be about the best for a detective camera, although lenses of shorter focus had some special advantages. Single lenses would also answer, but, he thought, scarcely so well as combination lenses. A Petzval lens on a small scale, as made for stereoscopic purposes, was excessively rapid. In answer to a question, Mr. Taylor added that he thought the best place for a stop when it was desired to avoid flare with portrait combinations was close to the front lens.

Mr. W. M. ASHMAN remarked that the best pictures taken in detective cameras which he had seen were taken by means of portrait lenses stopped down to one-half.

Mr. HENDERSON had hunted about in Paris to find a suitable make of lenses for a detective camera in which Mr. W. Cobb had an interest, and found a very neat little portrait lens which well answered the purpose.

Mr. TAYLOR stated that a correspondent had asked him what was the cause of spots on a print which he enclosed. Once a dry plate maker traced spots to dust from the indiarubber tube used as a water pipe; might not spots on prints arise sometimes from the same cause?

Mr. W. H. HARRISON said that indiarubber tubes were once made largely of French chalk, but that whitening is now substituted because it is cheaper.

Mr. A. COWAN opined that the whitening might be adulterated before the new start was made.

Mr. ASHMAN believed the spots in the print before them to be in the paper itself; there were at least twenty causes of spots, and the action of cold weather upon albumen was one of them.

Mr. TAYLOR said that dust falling from a powdery deposit on a gas jet had been known to cause spots; he thought that sulphur was one of the ingredients.

Mr. F. H. VARLEY said that if phenol were ever used for the coagulation of films of albumen, formic acid might possibly be evolved at places by decomposition and exercise a reducing action.

Mr. SMITH had obtained spots by examining the images in the printing frame under a dusty tree.

Mr. ASHMAN stated that albumenised paper kept long before sensitising was liable to produce spots.

Mr. HENDERSON said that washing in zinc troughs sometimes produced spots.

Mr. HEINRICH TRINKS thought that microscopic algae attacking albumen might possibly cause spots.

Mr. HENDERSON believed that the mixing of a light flocculent pigment with albumen would cause the latter to give better prints; the makers of albumenised paper should try it.

Mr. TAYLOR, returning to the subject of detective cameras, said that such cameras should be heavy; light ones were more liable to tremor, which could be reduced by fixing a stone to the camera; on the same principle a marksman

could shoot best with a heavy rifle. He had tried experiments on these points on the pier at Gravesend with a 5x8 camera, with which he took shoulder shots, and obtained negatives which would bear enlarging to three or four diameters; he used wide-angle lenses, probably of $\frac{f}{10}$ or $\frac{f}{12}$. He was practising level shooting, and found that he could get the horizon just where he wanted it, and that he could get any particular part of a passing ship at will in the centre of the plate; he intended to try 10x8 film photography in the same way. His shutter was of American make, and consisted of a rotating wheel with a hole in it.

Mr. J. J. BRIGNSHAW said that Mr. Lancaster made a shutter upon that principle.

Another question was, "What are the indications by which a paper negative is known to be thoroughly fixed?"

Mr. BRIGNSHAW could not see when paper negatives were properly fixed, so he left them in the bypo an unusually long time.

Mr. A. HADDON stated that in his experience it was as easy as with plates to tell when paper films were fixed, but the examination had to be made by transmitted light.

The Curator exhibited some ready-sensitised paper handed to him by the Association in December last to keep; it was advertised to keep well for nine months, and to be better than other commercial papers. It had discoloured to a great extent and was absolutely useless.

Mr. HENDERSON said that five or ten grains of citric acid added to each ounce of crystallised nitrate of silver would, when dissolved and used for sensitising, cause the paper to keep as well as most in the market; the error of most experimentalists was that they used too much citric acid.

Mr. TAYLOR remarked that Mr. Carey Lea had published that tartaric acid answered perfectly for the purpose. Paper simply floated on distilled water to remove excess after sensitising would keep its colour for a few days, and should be printed in a frame with a pad at the back which had been fumed in ammonia.

Mr. ASHMAN said that there were ready-sensitised papers in the market in a perfectly neutral state; he should like Mr. Henderson to tell them how papers could be preserved by the use of neutral salts.

The proceedings then closed.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

A SPECIAL Committee meeting was held at 181, Aldersgate-street on the 18th instant for the purpose of considering proposed alteration of rules.

Rule 4.—After "Donors of one guinea and upwards shall be entitled to vote at general and special general meetings, also at the election of pensioners," add the words, "and shall further have the privilege of recommending for the consideration of the Committee cases of non-members such as are defined as urgent in Rule 13," namely, "Urgent cases are limited to such as arose from death, sudden illness, fire, or other unavoidable calamities; also when the applicant has been out of employment for a length of time and requires aid to take a situation."

Rule 10. Committee.—To read, "They shall have powers at their discretion to grant temporary assistance to applicants or cases recommended by donors under Rule 4."

Mr. W. BEFORD, in moving these amendments, said he thought that donors should have this privilege extended to them, many of whom, having cases of distress brought under their notice, would prefer that the responsibility of dealing with them should be borne by an organized Benevolent Association, which would be in a better position to investigate the circumstances and to ensure the proper distribution of their contributions, and that by the alteration of rules empowering the Committee to act in such cases much good work would be done.

Mr. A. MACKIE, in seconding the motion, said he believed the alteration would result in increased donations, and therefore greater facilities would be afforded for carrying out the objects of the Association.

After considerable discussion the meeting unanimously adopted the proposition.

The special general meeting to confirm these alterations was fixed for Thursday, May 5, at half-past seven p.m.

At the ordinary Committee meeting Messrs. White, W. H. Dreaper, and G. S. Martin were elected members.

The SECRETARY read a letter from the London Stereoscopic Company, in which they stated their intention of holding their third annual exhibition in October next, which would be in aid of the Association, guaranteeing the benefit should not be less than twenty guineas, also making other proposals favourable to the Association.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of the above was held on Thursday evening, April 14, at the Free Public Library.—Mr. J. A. Forrest (President) in the chair.

Messrs. A. W. Taylor, Frank N. Eaton, and J. K. Smith, were elected as members.

The PRESIDENT soon had the members thoroughly *en rapport*, by the amusing narration of an adventure which befel an old gentleman a few days previously photographing some shipping on the Mersey; he had unwittingly fixed up his camera immediately in front of the electric cannon which supplies Liverpool with Greenwich time at one o'clock. While standing with his head under the cloth diligently focussing, Bang! went the gun, the old gentleman and camera making an ignominious exit over the dock wall into the river, and being still more ignominiously fished out on the end of a boat-hook, his first and last experience, he says, with the "wet process." Mr. Forrest also showed a frame of panoramic views embracing the twenty acres on Bidston Hill, which it is hoped will be presented as a Jubilee offering by the Corporation to the public. The photographs were mounted in a long cut out earl, the thin division between each not materially interfering with their continuity as a whole.

Mr. PAUL LANGE exhibited some specimens of the new form of stripped films just brought out by Messrs. Eastman. The negative being put on to

a collodionised plate of glass, the paper is stripped away by the ordinary method, and to the film remaining is squeezed one of the gelatine sheets prepared for the purpose. The whole, when dry and removed from the glass, forms an extremely thin and transparent negative. A number of prints were shown and received rather favourable criticism, as did the advantage in being able to attach the stripped films to a lighter medium than glass. Mr. Lange stated that he had found great care necessary in attaching the gelatine sheets, owing to their liability to cockle and warp.

The American air brush excited much interest on account of its novelty. It was ably demonstrated by Mr. G. E. BELL, the agent here for the American Company. By its aid in some five minutes he produced a life-sized drawing of a girl's head, which illustrated the beautiful gradations and depth of tone it is capable of rendering. A portfolio of finished drawings by him were very fine. To illustrate its usefulness in bromide and similar work Mr. Lange showed two platinum type enlargements of a head, the one finished with the air brush being immeasurably superior to the other. He said it had been found most useful in producing sky effects in paper negatives.

A number of specimens of phototype printing were passed round by the President and much admired, this process is a modification of the Heliotype, the stone being used as in lithography, any colour being obtainable. The results showed great definition and sharpness, and closely resembled the finest steel engravings.

Mr. JOHN HARGREAVES, F.R.H.S., gave the members the benefit of his researches in antiquarian lore by an amusing and descriptive account of places of historic and pictorial interest throughout Cheshire, with a view to the Association forming excursions to these spots during the summer, and so having a permanent record of their existence before they fall a victim to the tender mercies of the jerry builder.

A vote of thanks to Mr. Hargreaves brought the evening to a close.

DERBY PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of the above Society was held on Tuesday evening, April 12, at Sykes's Restaurant, 33, Victoria-street,—Mr. Richard Keene in the chair.

The subject of outdoor meetings for the summer months was discussed, and it was decided to hold the first at Dale Abbey on May 7. Mr. R. Keene will conduct the party and read a paper there on the history of the place.

The HON. SECRETARY read a recommendation from the Council to institute a competition at the outdoor excursions, and it was decided that the best picture (to be declared by vote of members) taken at these outdoor meetings be printed by the Society, and a copy presented to each member, and those receiving the second and third highest number of votes to be awarded a certificate, the whole to be exhibited at the annual *conversazione*.

Mr. J. C. MERRY then gave a practical demonstration on *How to Reduce in the Camera by Solar Light from Large Negatives for Transparencies for the Lantern*, which was greatly appreciated by the members present, and he was accorded a hearty vote of thanks.

By the desire of the members, Mr. Richard Keene will represent the Society at the meeting of the Photographic Convention, to be held at Glasgow in July next.

CHELTENHAM PHOTOGRAPHIC SOCIETY.

The monthly meeting was held on April 14, when a demonstration was given by Mr. JOYNER of the use of the magnesium light in portraiture.

The apparatus, of Mr. Joyner's own devising, consisted of a lantern constructed as follows:—A wooden box, having at top and back glass reflectors, and in front a sloping pane of ground-glass, was suspended from the ceiling. On the floor of the box was a horizontal gas jet, connected by rubber tubing with the gas supply. Just in front of the nipple was a small wire ring which held the lower end of the doubled magnesium ribbon, its upper end being attached to a hook vertically over the ring. The gas flame during the focussing was kept just alight, and when turned up ignited the magnesium wire. To supplement the illumination two other lengths of wire were burned in front of tin reflector placed at the side and a little in front of the sitter.

The duration of the light was about six seconds, and a very fairly-exposed group of eight members was obtained with a rapid symmetrical lens, full aperture. An excellent single portrait was taken in one second with the lens stopped down.

The demonstration showed clearly the great advantage that may be derived from this light, without any expensive apparatus or complicated details.

The question of the first excursion was settled in favour of Tintern, in May.

The Secretary exhibited an actinometer sent by Messrs. Green & Fudge, of Stratford-on-Avon, and two others by Mr. Stanley, of London Bridge.

A vote of thanks to Mr. Joyner brought the meeting to a close.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A REGULAR meeting of the above Society was held in the Mayor's Parlour, Old Town Hall, on the 13th instant,—Mr. George Bankart (President) in the chair.

The question of the approaching outdoor meetings was introduced and the members requested to give the matter their attention before the next meeting.

Mr. R. R. Blackwell was then called to the chair, and the PRESIDENT (Mr. George Bankart) read his paper on *The Influence of Little Things in Photography*. He opened by saying that numerous failures might be traced to inattention to small matters, which he instanced by the fact that dust on the plates was a fruitful source of trouble, and recommended that the transparent spots produced by it on the plates should be spotted out with a suitable medium before varnishing. Referring to exposure, he said that any hard-and-fast rule could not be laid down. One maxim he impressed on his hearers, always to expose for the shadows and let the lights take care of themselves. Development he considered secondary to exposure, as great range was permissible in this process, while in all he advocated extreme cleanliness, dirty trays being a prolific source of trouble. Exactitude in weighing and measurement was

strictly enjoined, and the rule of thumb in apportioning ammonia, pyro, and other chemicals, was much to be deprecated. Retouching he considered quite legitimate and very useful, as by its aid breadth was secured without flatness; in the case of high lights being too decided and demonstrative he recommended scraping the film with a sharp penknife and light touch to reduce them. He also advised, in landscape photography particularly, to avoid front light. He closed a clear and instructive address with a few useful hints as to printing and other matters connected with the art, and a vote of thanks was given with acclamation.

A discussion on the several points alluded to in the paper then took place among the members, their various experiences in the matters introduced being very useful.

The meeting was then adjourned until May 11, when Mr. Tucker will give his paper on *Lantern Slides by Reduction*, with practical illustrations, and from the experience he has had and the excellent work which has been produced from that quarter a very useful paper is anticipated.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

The monthly meeting of the above Society was held on the 15th instant,—Mr. S. W. Allen in the chair.

The election of the following gentlemen as ordinary members was confirmed:—Messrs. A. E. Evans, Powis, G. H. Wills.

The Society are indebted to Mr. D. Joshi for a promised lecture on the 27th instant on *Retouching*, concluding with remarks on Rembrandt and Dore pictures.

The Society's weekly excursions for May have been arranged as follows:—May 7, Aber Valley; 14, Reforest; 21, Llandaff; 28, Cardiff Castle. The latter will be subject to permission.

MANCHESTER PHOTOGRAPHIC SOCIETY.

LANTERN SECTION.

The usual monthly meeting of the Society was held at 36, George-street on Wednesday evening, March 23, at half-past seven.

Mr. JOHN SCHOFIELD (in the chair) said he had great pleasure in introducing Mr. Leach, who had made a life study of microscopy, and who intended to show his lantern microscope in operation that evening.

Mr. WILLIAM LEACH said it gave him very great pleasure to see so many scientific gentlemen around him, and he was sure the lantern and microscope had received their careful attention. He had devoted nearly twenty years of his life to the microscope, and in trying to improve that important accessory of the lantern. His knowledge was limited in the limelight details, and he would be obliged for any hints or instructions the members would give him, and in return he would tell them all in his power about magnification and the appliances to use. Mr. Grotorex therefore took charge of the limelight, and Mr. Leach described his improvements, and handed round a printed description of the details, &c. He then exhibited a number of the most suitable objects for the screen, most of which were mounted by himself and friends, and in all cases excited a degree of admiration.

A vote of thanks to Mr. Leach followed, after which the meeting terminated.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting was held in the Technical Schools, Bridge-street, Birmingham, on the 14th instant,—Vice-President, Mr. W. J. Harrison, F.G.S., in the chair. There was a good attendance.

Messrs. G. Birkett and A. Townshend were elected as members, and Mr. Robinson was nominated for election.

Mr. J. H. PICKARD read the report of the excursion to Bridgnorth.

Well, gentlemen, although our Chairman calls for the leader's report of our excursion on Good Friday, we really had no leader, our Mr. Welford being called away on business, so that the leadership was *nil*. As the time was too short to appoint another to take his place, and each member who went was practically his own leader, I have just dotted down a few notes I made at the time, which may be interesting to those who went and those who were left behind.

The start was made in glorious weather from Snow-hill Station with a contingent of twenty-nine members, all told—our Mr. Hill kindly taking up the position of rear guard—and arriving at Bridgnorth at thirty-five minutes past ten. This is a fine old town, many parts dating as far back as King Alfred's daughter, Elfreda, who is stated to have built the Castle. The ancient name of the town was *Brugis*; it is built on the banks of the Severn, which divides the Upper from the Lower Town. After ascending the hill from the station most of the members commenced taking the Town Hall and Market-place—a very interesting relic of old buildings. Nearly all of them seemed anxious to have this picture, for every possible straight and angular picture was attempted. The old "Swan Inn," next engaged our attention, with its swinging signboard (there seems to be no fine for obstructing the streets, as here). Proceeding on through the churchyard—the church could not be taken owing to the surroundings not giving room to get a picture, even with a wide-angle lens—then down a series of steps and slides, you might term them; for what with low, narrow steps and slippery blue bricks, many members had a fine opportunity for fancy drop-slutter work. We then reached the path by the river, passing along which numerous pretty bits and views were obtained, notably the High Rocks or Tor, and Flood-gates, &c. Crossing by the ferry-boat, and then along the Appleby road, we came to the Cemetery. This is one of the most picturesque spots one could imagine for the purpose (a kind of Swiss valley). Some of us ascended the path to the top of the High Rocks, finding a splendid view therefrom. Descending, and following the road to the bridge connecting the Lower and Upper Town, the different apparatus were soon set to work again. This gives a very good picture, with river and bridge as foreground, and the houses on the other side rising in tiers up the rock. Stopped by St. Stephen's Church, &c., myself, with the help of Messrs. Jacques, Taylor, &c., and a ferry-boat, gained a very good effect. On crossing the bridge we found an old timber house, said to have been Bishop Percy's residence—the date on it is 1320; but in this picture, as in most of the street views, we were cramped by the narrowness of the streets and hills: in fact, as Venice is built on the sea, so Bridgnorth may be said to be built on hills and steps. There is one passage with a quantity of steps cut through the solid rock from the Upper Town to the bridge; the former is sixty feet above the river and bridge. We then adjourned for lunch, and afterwards proceeded to the Castle Rock, on which stands St. Stephen's Church and the remains of the Castle. This has been twice besieged—once by Henry II., and again by the Parliamentary forces during the

civil war in the reign of Charles I. During the siege the Governor burnt the town to prevent the assaults approaching under cover of the houses. It was eventually taken and demolished, all but the tower. To destroy it undermining was resorted to, but the strength of the masonry and depth of the foundation only served to incline it some seventeen degrees out of the perpendicular, in which position it now remains. Many of the members took this in different positions. On passing round the Rock by the splendid Promenade Walk, very good bird's-eye views were found of the Lower Town, Bridge, and River, which could be seen winding its way through the surrounding country. We then reached the main street of the High Town, where sundry bits of views were had, such as the High Town Gate, which was once fortified, and finishing up with a group outside our hotel; and also a fine subject for a lantern slide, "King George of Bridgnorth," entitled "King Lear; or, Uncasy lies the Head which wears a Crown"—our friend, Mr. F. C. Taylor, kindly consenting to be crowned on the spot. Our repast was now ready for us by the host, Mr. Ensor, which was admirably served, and gained cause for recommendation to friends passing that way.

Reaching the station in time, Messrs. Holliday, Lewis, Iliffe, and myself, alternately had a shot at the whole party standing, sitting, and squatting on the opposite platform. I don't know how they got on, but think that my old friends—Dallmeyer, Ilford, and Beach—have helped me to win. Our train appearing, we entered the carriage and came back to Birmingham, all well satisfied with our inaugural trip of 1887.

The number of pictures taken was 180:—Ilford plate, 89; Fry's plate, 9; Wratten's, 2; Verel, 10; Banart, 11; Eastman film, 53; Morgan & Kidd film, 6.

A number of exhibits were shown by Messrs. Leeson, Harrison, Karleese, Jaques, and Pickard, of Bridgnorth, Warwick, and other places, and taken during the Easter holidays. Mr. Harrison also exhibited some very good photographs on china plaques made by Sampson, Bridgewood, & Son, Longton.

Mr. E. H. JACQUES then gave his paper on *Instantaneous Pictures and Appliances*. In the course of his remarks he said:—

I find when showing or exhibiting photographs that the greatest attention was called to instantaneous pictures—the great variety of subjects and naturalisation of effects lent a greater charm to the ordinary land or seascape, such as sea-waves, clouds, or ships, crowds of people and other living objects, and lately have turned my attention to this class of work. I will now proceed to show you how I got the prize pictures and the apparatus, &c., by which those and all my rapid negatives are done.

The lecturer commenced with the shutters, showing a large variety, beginning with the original drop-shutter down to the most modern ones of the present day, but said he preferred, and always used, the one made by Place. This, to his idea, gave very good exposure, both for foreground and sky, and almost any speed can be got with it. Passing on he came to the view finder, or rather spot finder, to enable one to see, say, for example, when on board one steamer to be sure of having another steamship on your plate even while the vessels are both tossing on the waves:—

Having gathered from our Mr. Forter's lecture some little time back some valuable hints as to composition and the strong (*forte*) points of a picture, I made a light wire frame and fastened across four black threads, forming a corresponding design of these points. This I place on the front of the camera, and at the back, over the focusing glass, I place a piece of flat brass, which, with hole in centre, forms the eye-piece. Now, having focussed for a certain distance, I insert the slide and open same, then holding the camera by the hand (resting it on the legs to steady it), I look through the eye-piece at the frame with the crossed threads, and the moment the object required comes across the points wanted, loose the shutter with the pneumatic release, and the result is always correct.

He next spoke of having had his best successes with Paget and Ilford rapid plates, and recommended slow development, and gave the developer he uses.

A.

Carbonate of potash	8 ounces.
Oxalate of potash	6 "
Water	30 "
Sulphuric acid	3 drops.

B.

Sulphate of iron	4 ounces.
Water	10 "

Use one part of B to four parts of A.

To accelerate or complete the development, use drops as much as needful of
Bromide of ammonium 1 drachm. || Ammonia | 1 " |
| Hypo-sulphite of soda | 10 grammes. |

He also recommended the Paget developer. The lecture was interspersed with numerous practical hints and illustrations, and was listened to with great attention and benefit.

A long discussion followed, in which Mr. Jaques gave great help, and the meeting ended by the CHAIRMAN announcing the subject of the next paper by Mr. F. Birkett, *Printing by Artificial Light*.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Society was held on April 7 in the Philosophical Society's rooms, 207, Bath-street.—Mr. William Lang, jun., F.C.S., occupied the chair.

After the preliminary business had been disposed of the following gentlemen were elected members:—Archibald Watson, Peter Anderson, Adolf Schulze, Thomas Taylor, and R. B. M. Stewart.

Thereafter the nomination of office-bearers for next session took place.

Mr. G. BELL showed some prints which were very much mottled, and explained that up to the time of coming out of the fixing bath they appeared all right, but after that the surface became quite soft, and got rubbed off in the subsequent washing. He asked if any of the members could assign a cause for this, or if any one had been troubled in the same way? The general opinion was that the silver bath was weak, and so caused the mottling complained of. Mr. Bell, however, stated that with the same bath prints that had undergone the same treatment were not injured in the least, and his opinion was that the albumenised paper was at fault. He had brought them with him, thinking it would cause some discussion, but seeing there was so much on the programme to-night, he thought it would be better to allow the matter to drop at this stage and proceed with the other business.

The PRESIDENT thereupon vacated the chair for the purpose of reading his paper, entitled *Photography and Book Illustration* [this will appear in a future number], and Mr. Urie acted as interim chairman.

The paper in question proved of most exceptionable interest, the books mentioned therein being handed round for the inspection of the members.

At the close of the paper, Mr. Urie said Mr. Lang had given quite a history of the illustrating of books with silver prints from the time of Talbot down to the present day. The specimens of Talbot's were standing well while those by our own townsmen showed that Glasgow was not lagging behind. He hoped Mr. Lang would, early next session, bring forward the paper he had promised on *Books Illustrated by Other Printing Processes*, which would be of as great interest as the one they had listened to. He trusted the members would now consider the meeting open, and that they would take advantage by making any remarks or asking any questions they wished on the paper.

Mr. BELL said that the valuable collection of books shown by Mr. Lang to-night must have cost him considerable trouble and expense in gathering, and he thought Mr. Lang was to be envied as the possessor of such a fine series of illustrated books. It was a pity, however, to see so many of the pictures fading.

Mr. ARMSTRONG thought the bulk of the prints were not very far gone, considering the age of many of them, but he noticed in the later published books the fading was most marked.

Mr. STEWART mentioned that one of the Ettrick Shepherd's poems had some beautiful illustrations by the London Stereoscopic Company, and he thought the views by Frith were in the best state of preservation of any. In connection with Frith, he might state he had brought an album with some of his Eastern pictures, and the members might see it at the close of the meeting.

Mr. BROWN thought the illustrations were in a better state of preservation than many pictures done only twelve months ago; he thought this was due to the long toning they had received, depositing a quantity of gold on the surface of the prints.

Mr. Urie then moved a vote of thanks to Mr. Lang for his excellent paper, which was heartily responded to.

Mr. Lang having resumed the chair, a number of specimens of isochromatic photography from Mr. B. J. Edwards, London, were passed round, and elicited the praise of all present for their wonderful rendering of colours. One especially, an oleograph, was considered conclusive evidence of the advantage of isochromatic plates when used instead of ordinary plates for copying paintings. This picture was of a most non-actinic colour, being composed almost entirely of different shades of yellow, but yet with the use of these plates had rendered an exceedingly good photograph. When all had seen and admired these specimens, a vote of thanks was given to Mr. Edwards for so kindly sending them for inspection by the members.

Mr. Lang showed a number of early calotype negatives and prints from same, which were said to be Talbot's, and after the members had examined these and also the album brought by Mr. Stewart the meeting separated. It was to be regretted, considering the interesting nature of the meeting, that there was not a larger attendance.

PHOTOGRAPHIC SOCIETY OF INDIA.

A GENERAL meeting of the members of the Society was held on the 9th ultimo in the reading-room of the Dalhousie Institute at fifteen minutes past nine p.m. There was a good attendance of members.

Mr. JOHN S. GLADSTONE, one of the Joint Secretaries, opened the meeting by giving a short *resumé* of the working of the Society since its birth. He said that the Society was started in March, 1886, that Committee meetings had been held from time to time, and that the present was the fourth general meeting. At some of the earlier Committee meetings the question of holding a public exhibition in Calcutta during the cold season of 1886 had been discussed, but it was eventually decided to defer it until the end of the current year, and instead to invite members to send specimens of their work for private exhibition. A circular was accordingly issued to this effect. In response, about eighty pictures had been submitted which were now on view in the room. The Committee considered that these photographs were certainly a credit to the exhibitors. With regard to the future, an enlarging lantern of the newest design had been ordered from England, and would, no doubt, prove of great use to members. Mr. Gladstone then called upon his colleague, Mr. A. FLEMING, to inform the meeting of the financial position of the Society.

Mr. FLEMING said the Society at present numbered about sixty-five members, and financially might be considered to be in a prosperous condition. He was glad to observe that the number of members was increasing steadily. He regretted that considerable delay had occurred in putting the Society on a working footing. He was glad, however, to report that all difficulties had now been overcome, and there was every reason to hope that the success of the Society had been assured.

Sir BENJAMIN SIMPSON, M.D., who had kindly responded to an invitation to address the meeting, then gave some very practical and pithy advice on the best means of developing some of the objects for which the Society had been inaugurated. The proposal to secure a central and convenient place for members to meet, he thought, might be best arranged in communication with Colonel Waterhouse. The old Bengal Photographic Society used to meet in the rooms of the Asiatic Society, and he suggested that Colonel Waterhouse, who was also President of that Society, might be asked to use his interest to procure for the Photographic Society of India the privilege of meeting in the Asiatic Society's rooms. With regard to the proposed annual exhibition of photographs, he was afraid that the attractions of the cold weather season would render the exhibition in Calcutta hardly so successful as one in Simla. But, on the other hand, the space at the rooms of the Simla Society of Fine Arts was too limited to warrant him recommending the Photographic Society to seek to hold their annual exhibition there, so, on the whole, he thought if the Society made the exhibition a very interesting and varied one, by being liberal in their prizes, Calcutta in the cold season would be the best place to hold it. There were, however, many members living on the other side of India who would be debarred from judging the progress of photography if these exhibitions were restricted to Calcutta, and on this account he would suggest that the best of the collection, including the prize photographs, should be sent every year for exhibition to Simla. The young Society, he thought, should be careful to attract members by avoidance of anything tending to localise the

scope of its usefulness. It was indispensable to success that its influences should be felt throughout India. It professed to help all who cared to embark on the fascinating study of photography, and he had no doubt that the Committee would bear this in mind. A great deal was to be done by correspondence, especially in the exchange of good photographs and apparatus between members. He thought that an opportunity should be sought to foster the publication of whatever was interesting and profitable, connected not only with the Society itself, but with photography in India generally. The proposal to send each member a copy of the photograph selected by the Committee, as the best specimen submitted to the private exhibition, was an excellent beginning of the real work now being done by the Society. He looked forward to the time when the Photographic Society of India would have more than fulfilled the objects for which it had been inaugurated.

After a pleasant evening the meeting separated, having first proposed a vote of thanks to Sir Benjamin Simpson for his advice.

Correspondence.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—With reference to Mr. Rattray's letter on this subject in your last issue, I do not see that the instance he gives respecting the engraving of a copperplate to order, bears upon the subject at all. When a client gives an order for a copperplate to be engraved for a business card, or any other purpose, he does so with a full knowledge that the plate will be his own property; he is told the cost of the plate and the cost of the cards, or what not, but with photographers this is not so. When a client comes into the photographic studio and inquires the price per dozen of *cartes-de-visite*, or cabinets, as the case may be, he is quoted for what he asks, namely, the pictures and not the negative. Of course, when a photographer fixes his prices he includes the cost of the negative in his working expenses, as he does all other expenses incurred in the execution of the work, but I fail to see that he forfeits his right to the negative for that reason. It has simply been *his means* of producing the work ordered. Upon the same principle one might give an artist an order to paint a picture and then demand his brushes, as having been the means of producing the work; and I presume an artist, when quoting a price for work, has to take into consideration the cost of his materials, the same as a photographer or any other business man.—I am, yours, &c.,

73, Grove-street, Derby, April 18, 1887.

E. J. LOVEJOY.

To the Editors.

GENTLEMEN,—With regard to the question of the ownership of the negative, I remember some time back a case was tried regarding the ownership of a negative of a building, the invoice having been made out,—

To taking negative and — copies £

It was held on the face of the invoice that the amount charged included the negative and it was ordered to be given up.

With regard to the ordinary practice, as the price list is for so many copies, as soon as the copies are delivered and paid for the contract is completed; no reference having been made to the negative in the contract it would appear the client cannot claim it.

In Paris a case has recently been heard in which Count D'Agoult brought a suit against M. Adam Salomon, and claimed the negatives of several members of his family, and judgment was given that a photographer cannot exhibit nor sell the portrait of his customers without their consent, but it has also decided, on the other hand, that the negatives belong to the photographer, and cannot be claimed by the sitters.

I regret just at the moment I cannot recall the names of the parties interested in the first instance quoted, but will have another search through my papers, and if I can find the case will let you know at once.—I am, yours, &c.,

G. S.

META-BISULPHITE OF POTASH.

To the Editors.

GENTLEMEN,—I must thank your correspondent, Mr. J. Whitfield, whose letter I see quoted in your "Answers to Correspondents," for reminding me that I ought to have mentioned in my paper on *Rational Development* that the use of meta-bisulphite of potash entails an extra amount of alkali in development. I was not aware before I read the said quotation of the exact proportion of alkali neutralised by the acid, for I never actually tested it.

Having made further experiments of late, I find that even half the quantity of the potash salt will preserve the pyro, that is to say, half an ounce of the bisulphite will keep one ounce of pyro in ten per cent. solution quite clear for a long time; I have not yet got beyond two months. Possibly even less of the potash salt will serve the purpose practically. But in all cases Mr. Whitfield's warning must be kept in mind, namely, that extra alkali is required. If the sulphite of soda, or what is called "sulpho-pyrogallol," be over acidified the result will be the same. The reason is obvious and identical in the two cases.

My chief reason for preferring the potash to the soda solution is that the former is more easily, speedily, and certainly prepared. The sodic

sulphite is used in larger quantity, is not easily dissolved, and requires careful neutralisation with acid, while the other is simply dissolved with complete ease and needs no further treatment. In use the one seems to be as good as the other.—I am, yours, &c.,

ANDREW PRINGLE.

Langholm, April 16, 1887.

A FORTHCOMING AMATEUR EXHIBITION.

To the Editors.

GENTLEMEN,—Will you allow us, through the medium of your columns, to acquaint those of your readers who may be amateur photographers, that it is the intention of this Company to hold its third Annual International Photographic Exhibition some time during the autumn months, particulars of which can be obtained on inquiry? We purpose giving away in prizes the sum of £50 (in cash), together with a number of gold, silver, and bronze medals; we have decided to make an entrance fee of 2s. 6d., which sum, together with all donations collected from the boxes, will be handed over by us in full to the Treasurer of the Photographers' Benevolent Association. Last year some hundreds of amateurs competed, and as we this year have every reason to anticipate an equal or even greater success, we should be enabled to hand to the Association a fair sum.—We are, yours, &c.,

THE STEREOSCOPIC AND PHOTOGRAPHIC COMPANY, LIMITED.

51, Cheapside, London, E.C., April 19, 1887.

COLONIAL GRIEVANCES, &c.

To the Editors.

GENTLEMEN,—I was very glad to see that a Colonial Photographic Society took up the question of the trouble one experiences in obtaining from England supplies of photographic material.

In 1881 I wrote two or three letters from Madras to a journal on the same subject, and for a year or two after that time I continued to experience similar delay, but since 1883, I am thankful to say, I have dealt with a firm who invariably owns receipt of letters and remittances by return of post and sends out the goods within two weeks of receipt of order; another firm has also sent me out supplies of most excellent sensitised paper with the strictest regularity.

"Monitor" implies that ordinary chemicals are as readily obtainable in any of the big cities in the Colonies as in London. This is not the case, for I have frequently tried to obtain such ordinary chemicals as "sulphite of soda," "chloride of platinum," "bromide of zinc," "chrome alum," &c., but failed so far as Madras and Bombay are concerned.

In your JOURNAL of the 8th instant, there appears a communication from Colonel Waterhouse, giving details of arrangements for developing gelatine plates in hot climates. For many years in Madras I used similar precautions, but early in 1886 I found I could develop my plates *without the use of ice at any stage*, by merely adding to each two ounces of developer thirty to sixty minims of chrome alum saturated solution.

With this addition I developed one dozen plates, one morning last August, in Madras, when the temperature of my dark room must have been considerably over 100°, and not a sign of blister or frill was to be seen. The plates were Edwards's special instantaneous.—I am, yours, &c.,

MADRAS.

9, Campbell-terrace, Southsea, April 20, 1887.

PHOTOGRAPHIC EXHIBITION IN AUSTRALIA: AN INVITATION.

To the Editors.

GENTLEMEN,—Will you kindly allow me space to inform members of the many English Photographic Societies, that the Annual Exhibition of the Victorian Amateur Photographic Association will be held in Melbourne in the beginning of July next?

I am authorised to invite contributions from British Photographic Societies, the Committee guaranteeing the utmost care of all exhibits, either returning the same, or, if so desired, will exchange print for print for Australian pictures. Book and Parcels' Posts to the Australian Colonies now render transition inexpensive, easy, and with careful packing, quite safe.

I trust this opportunity of extending the right hand of photographic fellowship will not be allowed to pass without result, and that it may prove but the introduction to future courteous interchanges between the Societies of the Mother Country and those of the Colonies. All communications and consignments (which must leave by the last May mail at latest) should be addressed to the Hon. Secretary, Mr. J. H. Harvey, 83, Gore-street, Fitzroy, Melbourne, Australia. I shall be most happy to supply any further information.—I am, yours, &c.,

EDWARD W. PURTON, Custodian, Amateur Photographic

59, Rochester-road, Camden-road, N.W.

Association, Victoria.

PERKIN, SON, & RAYMENT wish us to call attention to a slight printers' error in their *Beginner's Guide to Photography*. In the Tables of Weights, Measures, &c., on page 63, twenty minims are given as being equivalent to one fluid drachm; this, of course, should read sixty minims equal to one fluid drachm.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

- J. L. Denny, Daventry.—Two portraits of Mrs. Sarah Harris.
B. Duckmanton, Gainsborough.—Four portraits of Dr. Bagshaw.
James Brown, Dundee.—Two portraits of Rev. D. Macrae.
G. W. Wilson & Co., Aberdeen.—Views of Rosstyn Chapel, &c.

M. WHITING.—Received.

RECEIVED.—J. D. Cooper. In our next.

W. A. BRICE.—A private letter is being sent.

T. M.—The negative seems to be too thin. Give shorter exposure and develop longer.

THOS. K. FAIRLESS.—The moonlight effect is obtained by the agency of dyes, such as Judson's.

RECEIVED.—We have received samples of printing paper from several dealers or makers. Among others two samples of exceedingly quick printing paper from Marion & Co., on which we shall report next week.

A SUBSCRIBER.—The marks proceed from the silver not being uniform all over the paper. Some of the sensitising solution has apparently flowed over the paper a second in the form of streaks, or it may be across the back of the paper.

RUSSELL STEELE.—Either the A, B, or C lenses will answer. The B will be the more rapid in action, the A next, and the C the slowest. The last lens named in your list is less suitable than either of the other three for standing figures.

TYRO.—Yours is a decided case of halation. The way to avoid it is to employ plates with a thicker coating of emulsion, or to "tack" the plates by coating them with sienna mixed with water containing just sufficient dextrine to prevent the colour from rubbing off when dry.

RECEIVED.—Three steel portraits of Her Majesty the Queen, representing her at the ages respectively of eight, eighteen, and (presumably) twenty-eight, have been received from the publishers, Charles & Co., Salisbury-court, Fleet-street. These will find favour with many persons.

W. W. H.—The subscription for the JOURNAL posted weekly to Germany for a half year is 8s. 8d. The prints indicate taste in selecting the point of view, but the foliage in the picture of the house is much too dark. The trout-stream is pictorially and technically excellent.

L. BOURQUIN.—You do not say what the clothes are stained with. Different stains require different treatment. If the garments are very light in colour it is possible that they will have to be dyed of a darker shade, as chemical stains cannot always be removed without injury to the fabric.

F. B.—1. You will not require a license for your stamp unless it bears a crest.—2. If you have paid for a die to be engraved it should become your property. Perhaps you are, however, only charged a small sum for writing on the stone.—3. To obtain more gloss, use the gum water stronger. Messrs. Newman & Co., Soho-square, publish a work on colouring.

SQUARE.—We have referred to the article alluded to. It would take up a great deal of space to go fully into the matter, and it would not be of interest to our readers. The subject is only interesting to a very few who follow a particular branch of photography as a business, and they are well informed on the point already. Perhaps one or other of them will give you instruction for a consideration.

LOLO.—The spots or markings are due to want of care in the fixing. The prints have been allowed to stick together while in the fixing bath, and so set up a sulphuretted action, hence the yellow markings. The backs of the prints show evidence of having been carelessly handled with fingers contaminated with hyposulphite of soda. Greater care in the manipulations will avoid such markings in future.

G. FROST.—Very much will depend upon the aspect of the windows. One thickness of ruby and one of orange will probably be sufficient. But if it face the south another thickness of ruby may be required. The lenses named will answer, though they will of course be much slower than a portrait combination. The only houses we know for picture frames are those whose advertisements appear in the business pages of the JOURNAL and ALMANACS.

KUNZ BROS.—We are not aware of any method by which the paper can be made as sensitive as you require except by gelatino-bromide emulsion. To avoid the gloss, the gelatine must be reduced to a minimum. Some of the paper prepared by the Eastman Company has very little gloss indeed, and is much used for finished work. If it were possible to obtain less gloss than this paper possesses the image would, no doubt, have a "sunken-in" and flat appearance.

C. ROWLAND writes: "Would you kindly explain the following in the next issue of your JOURNAL? A friend of mine took two interiors a little while ago of a chapel in the neighbourhood; he developed one the same evening; it was much over exposed, and, to use his own words, 'the image was on the plate before placing it in the developer.' I thought he must be mistaken. A few days after he came into my room with his plate box in his hand, and, not caring to develop the other of the two plates because it had had a longer exposure than the first, took it out to throw away, when, looking at it, he called me, and on the plate I distinctly saw the window of the chapel with the gas fittings which were between the window and camera. As we looked at it gradually faded away, and in less than three minutes was gone. If you can elucidate this (to me) mystery you will much oblige."—When a plate or part of a plate (in this case the window) is very much over exposed, it is not an unusual thing for the image to be faintly visible before development. The cause of its disappearance was that the action of the light on the film darkened it and so buried the faint image.

PARCHMENT.—1. For a license to print apply to the Office of Inland Revenue.—2. We cannot offer any suggestion relative to the parchment.

FERROTYPES.—1. The silver may be precipitated as a chloride by adding solution of chloride of sodium.—2. An ordinary camera as described will answer for ferrotypes.—3. Such a studio as described will serve for taking groups.—4. *Trask's Practical Ferrotypes* is an American manual, which may be obtained from or through Atkinson, of Liverpool.—5. The quickest way by which to produce prints is that described in an article in ALMANAC for current year entitled *How an Order was quickly Executed*. [See page 229.]

C. M. B. asks: "Will the formula you give in the leading article of the last number of the JOURNAL for developing gelatine plates used for copying line subjects, together with preliminary soaking in a two-grain solution of gallic acid, suit equally a batch of plates which have been exposed to about double the correct time? If not, what course do you recommend me to pursue? The subjects are landscape and architectural."—The plan recommended will possibly answer quite well. If the plates have a tendency to frill with the potash developer then the ammonia may be substituted. If the plates are very much over exposed a still larger proportion of bromide must be used.

F. S. asks: "Can you help me out of the undermentioned difficulty? I have some copying to do, and I have tried by wet process, but the fogging by the carriers spoils everything. They have silver wire corners; one is new and the other is old, but both give the same result."—The trouble complained of is no doubt what is known as "oyster-shell markings." One of the principal causes of this evil is due to the collodion being of a horny and repellent character. The best plan for our correspondent to pursue will be to add some old and porous collodion to that he is now using, drain the plates very closely before placing them in the slides, and to see that they rest on strips of blotting-paper so as not to touch the woodwork of the carriers at all.

D. G. THOMSON, M.D., writing from the Camera Club, states a case *oppos* of some remarks made by "Free Lance" in the JOURNAL for March 11. He says: "A lady went to Mr. Blank's studio in a suburb about this time last year and sat for cabinet portraits in several positions. Six were ordered and paid for, proofs were sent in due course, and so many copies ordered of each. Unknown to and without the permission of the sitter, a large direct negative was taken at the same time—I forget the size; I should think 16x12—and a letter sent subsequently to the effect that Mr. — had at the same time taken a large photograph, and submitting a print of it for sale at three guineas. Although admired as a picture by the lady and her friends, it was refused. Again without the permission or knowledge of the lady, it was sent to a certain photographic exhibition, and was awarded a medal for portraiture. The lady's friends wrote to Mr. — remonstrating with him for taking this liberty, and received an unsatisfactory and evasive answer, with a refusal even to make the *amende honorable* of sending the lady a copy of the picture. This should be exposed, namely, the dodge of taking a number of negatives, keeping the best one back, and submitting it later for sale, it having already been paid for as a sitting. He has furthermore annoyed the lady ever since by prominently exhibiting this portrait in his shop. No disagreeables would have arisen had Mr. — had the ordinary civility and courtesy to ask permission first. Mr. — cannot construe the fact that on the lady calling at his studio one day he informed her that her portrait was in the exhibition, and that he foisted two admission tickets on her acceptance, into permission asked and granted. Will you kindly inform me if by any means I can recover a copy of the sitting, which, as one of the rest, was duly paid for, and also if I can cause Mr. — to cease exhibiting the lady's portrait in his shop?"—In the foregoing we have for obvious reasons suppressed the name of the photographer, his residence, and the exhibition. We are sorry to have to say that this practice is not altogether unknown even with firms of recognised respectability. There is no denying that it is highly reprehensible, and cannot be too strongly condemned. Concerning the legal aspect of the case, we invite expressions of opinion.

CAMERA CLUB.—The subject for Thursday, April 28, is *A Photographic Tour to the Spanish Main*, with lantern illustrations, by Mr. Lyonel Clark.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, April 27, 1887, will be *Lantern Matters*. This is a lantern night. Visitors are invited.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next technical meeting of this Society will take place on Tuesday next, April 26, at the Gallery, 5A, Pall Mall East, when the subject of *Stripping Films* (with demonstrations) will be brought forward.

PHOTOGRAPHING THE STATE APARTMENTS AT WINDSOR.—During the past week Mr. William Brooks has been actively employed in taking negatives of the State Apartments, and so far as he has yet gone he has, we learn, been very successful. Mr. Brooks anticipates that they will make a fine lantern series.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1408. VOL. XXXIV.—APRIL 29, 1887.

RECORDING TIME AUDIBLY.

It is confessedly troublesome to impress the eye into the marking of brief periods of time, especially when that organ should be otherwise engaged. Those who have astronomical observations on hand require the ear as well as the eye to be on the alert.

It was probably some such feeling as this that prompted Mr. Lyonel Clark to devise an audible time marker of the simplest construction, yet most exact nature, which he exhibited last week at the Camera Club. It was only a pendulum and very little more; but that little was everything. Started into action by a push of the finger, a well-suspended pendulum, having a ball or bob of moderate weight, will go on oscillating for a long period, until brought to a stop by the operation of the law of gravity and the atmospheric resistance.

Mr. Clark's invention—if invention we may designate it—consists in supporting a half-seconds pendulum on a table stand, on which stand projects, at a right angle to the motion of the pendulum and a little below the pendulum ball, a slip of steel or other hard sonorous metal, which when touched by any passing body shall emit a sound partaking of the nature of a ring, or at any rate a well-developed clink.

Suspended to the lower end of the pendulum rod is a bit of string of, say, an inch in length, which sustains a bit of any hard metal. Alas! that we have to record it, but on this occasion it was only a brace button, which will answer quite well. This goes flipflap against the interposing strip of metal and records its transit quite audibly.

To beat seconds there must be a distance of forty inches (less a portion of an inch) between the point of suspension and the centre of the pendulum ball, which gives ten inches as the length of a pendulum rod that is required to indicate half seconds; and, as we have said, if the ball be of sufficient weight, when once it is started by a vigorous push it will continue vibrating for a long time, recording half seconds audibly with the greatest regularity. It is immaterial whether the oscillations of the pendulum be great or small, so long as the suspended button strikes against the projecting bar, for the vibrations are isochronal, the long and short ones being performed in equal time.

The appliance here described, simple though it be, will, we believe, conduce much to the comfort of those who are conducting experiments which involve time exposures in the laboratory, and Mr. Clark deserves thanks for bringing it forward.

THE INTENSIFICATION OF GELATINE NEGATIVES.
SINCE we wrote a fortnight ago on the subject of *Gelatine Plates for Copying Line Subjects*, we have had several proofs

that a satisfactory method of utilising rapid plates for the purpose is much needed; and though Mr. Bolas, in his discourse on photo-mechanical printing methods before the Camera Club on Thursday evening last week, made no allusion to the production of the negative, there is no gainsaying the fact that the operation presents difficulties to many.

So far as general practice is concerned, it is not found, as we stated in our article a fortnight since, that ordinary rapid gelatine plates lend themselves with any particular readiness to the purposes of black and white, or, indeed, other reproductions where extreme density is required, as for photo-mechanical purposes. The reason of this is chiefly that the modern plate is made for rapidity and softness of gradation rather than for vigour and contrast, and that without some special mode of treatment, such as that given in the article to which we refer, it is undoubtedly inferior to wet collodion. There are, it is true, many methods of intensification, but all, or most of them, appear to possess some objectionable features which render their employment unpopular.

Our own predilection has always been, as we have frequently stated in these columns, in favour of what is known as "silver intensification," that is, the employment of an acidified solution of pyrogallol to which a small quantity of silver nitrate is added. The results obtained by this method are, we think, beyond all doubt superior to those obtained by any other, and its only fault, if fault it really be, lies in the care which is necessary in order to avoid staining the negative. This stain is as easily preventable as any other kind of stain, and when the negative has been successfully intensified, the image, as we have proved by the test of seven or eight years, is reasonably, if not absolutely permanent, a distinct contrast to many other modes of intensification, which, if they do not lead to immediate discolouration, lay the seeds for subsequent and not very distant decay.

Consequently, on our predisposition in favour of silver intensification, we hailed with delight a novel method for which most favourable claims are made in the report of the Photographic Society of Philadelphia in another column, and lost no time in putting the process to a careful test, but with, we regret to say, an almost total want of success. In fact, we cannot help thinking that the plan as detailed in the report has got unfortunately muddled, for a more extraordinary want of agreement between results promised and obtained it would be difficult to find, while the conditions laid down are equally surprising.

In principle the method involves the substitution of gallic acid for pyro, and this is the feature which specially attracted us, though it is by no means new, M. Jastrzembki having

some years ago published a process specially adapted to gelatine plates in which gallic acid, acetic acid, and silver were employed, the silver solution being acidified previous to its mixture with the reducing agent. But in the method which comes to us from Philadelphia a different course is adopted, the negative itself being submitted to a preliminary acid bath previous to the application of the gallo-nitrate solution, which is used unrestrained. Now, as a consequence, the intensifier depends entirely upon the quantity of acid absorbed by the negative film for any restraining influence to prevent abnormal reduction. The solutions of silver and gallic acid, if mixed before application to the plate, become instantly discoloured and muddy, a condition which increases as the operation proceeds, and consequently tends greatly to staining the negative.

Further than this, the preliminary acid bath so far from reducing the chances of staining by contact of silver with unremoved hypo, actually increases the probability, since any hypo remaining on the film would be resolved into dangerous sulphur compounds more to be avoided than the hypo itself. There is, moreover, apparently some discrepancy in the respective quantities of the different acids mentioned in connection with the preliminary bath, for ten minims of even the strongest nitric acid can scarcely be accepted as a fair equivalent for *one ounce* of citric acid; nor can the latter, a definite crystalline substance, be compared weight for weight with such a variable and uncertain liquid as "acetic acid."

But perhaps the most serious objection to the preliminary bath consists in its other constituent—the chrome alum. The immersion of the plate in a solution of chrome alum of the strength of one ounce to the pint, or upwards of twenty grains to the ounce, exercises such a hardening effect upon the film that all chemical or intensifying action is practically arrested, and the only effect of even a most prolonged immersion is to *stain* the image, and so give it a fictitious appearance of greater density. The fixing operation, too, is so seriously prolonged from the same cause that despite the combined hardening effects of the chrome alum and the gallic acid, frilling can scarcely be prevented.

Even greater anomalies exist in the intensifying solution itself. Stock solution A we are told is composed of 120 grains of gallic acid dissolved in one ounce of alcohol, or, roughly, one part in four, and one drachm of this solution is to be used to each ounce of intensifier. But in the first place we do not find it possible to dissolve anything like the quantity named, and even when the alcohol is allowed to take up as much as it will a portion of it is precipitated when water is added. If the strength of solution were correctly stated then the dose of gallic acid—fifteen grains to each ounce of intensifier—is an unmistakably "stiff" one and one that will scarcely recommend this method on the score of economy. Add to this that the proportion of alcohol in the intensifier is so large—one drachm to the ounce—that the film partially rejects it, a circumstance that acts as a further arrest to chemical action as well as tending to inequality of action, for the solution runs off the plate in the same "greasy" manner that the silver bath does from a freshly dipped collodion plate.

Then, lastly, as we have pointed out, neither the gallic acid nor the silver solution contains any restraining acid, consequently, instantly they are mixed the silver commences to suffer reduction. The discolouration that ensues is not of the character that occurs when nitric, acetic, or citric acid is present and when the solution, though it darkens, remains per-

fectly clear for a considerable time. On the contrary, the result is a filthy mixture of a dirty black colour, that from the first leaves a dense sediment adhering to both developing dish and plate, and which is in itself sufficient to ruin any negative however good.

As the result of our experiments it will not surprise our readers, then, if we say that the method as given has proved an entire failure, though, be it said, we do not imply that gallic acid properly applied cannot be employed for the purpose, and perhaps with certain advantages over pyro. But the preliminary bath as at present recommended, and the absence of restrainer in the intensifying solution, entirely destroy any possible advantages derivable from the Philadelphia formula.

As an example of the working of that formula we may quote an actual experiment. A plate was cut in half and one portion treated with *six* successive portions of freshly mixed gallic acid and silver solutions during a period extending over nearly three hours, the solution being replaced when it seemed impossible for it to discolour any more. The final result was simply an alteration of the general colour of the negative arising from the staining of the film, and when printed from the two halves of the negative showed precisely the same amount of contrast, though the "intensified" portion took three times as long to print.

We may shortly return to the subject of gallic acid intensification, but at present we can scarcely recommend the adoption of the plan referred to.

BACKGROUNDS BY THE "POWDER PROCESS."

IN recent articles we have given the practical details for preparing backgrounds by two different methods, namely, in flatted oil and in distemper colour. We now propose to describe a third plan, which, for want of a better name, we shall designate the "powder" or "dusting-on" method—terms not altogether unknown in photography—inasmuch as the colour is applied to the canvas in a dry and powdery condition.

The principle of the method is this. The pigment, as a powder, is mixed with an adhesive material, also in the dry state, and then applied to a moist fabric and well incorporated with it. Hence, when finished, the colour becomes fixed. By this system a background may be produced which is equally as efficacious as by either of the previously described methods, while, at the same time, the plan possesses this advantage over them, namely, that graduated tints may be obtained without difficulty. It may be mentioned that backgrounds made by this process are not quite so durable as those in oil colours, but they are equal in durability to those in distemper, if, indeed, they are not much superior. The powder process has the further advantage over the flatted oil or other methods, that, in case of injury, the background can easily and quickly be repaired, very frequently without a fresh application of pigment.

Furthermore, the manipulations are so simple that the novice is scarcely likely to fail, even with his first attempt, which can hardly be said with reference to either distemper or flating. This process, though a very old one, does not appear to be very generally known. It was introduced first, we believe, by Mr. A. H. Wall more than a quarter of a century ago, and it has since then been vended, for a substantial fee, as a "secret process." Here is the method of procedure.

A piece of unbleached sheeting, such as that generally used for backgrounds, is strained on a wooden frame in the usual manner. Next the colour is prepared. The particular pigments

employed will, of course, depend upon the taste of the operator. Colours such as those used for distemper will answer quite well. Common whiting, lampblack, umber, Venetian red, are all good pigments for the purpose. Whatever colours are used it is essential that they be reduced to a state of fine powder, and then blended to the tint desired. When the right tint is obtained, a small quantity of dextrine is added and intimately mixed. The proportion of dextrine to be added cannot be definitely stated—for the same reason that the exact quantity of size required for distemper could not be given in a former article—so much is dependent upon the pigments employed. One or two experiments on a small scale will determine the matter, particularly as a wide margin is allowable. If too little dextrine be added the colour will rub off when the background is finished. An excess, however, within very wide limits, will be of little moment; therefore, it is better to err on the side of using too much than too little.

It is a good plan to prepare a large quantity of colour at a time, as it will keep indefinitely if preserved in a dry place. The advantage of doing this is, that if at any time a lighter or darker background be desired, all that is necessary will be to take some of the stock colour and add to it either some white or black according to the shade required. The colour is applied as follows:—

The frame, with the strained canvas upon it, is laid flat upon the floor. The fabric is then evenly wetted with water, not merely damped, but it understood, but made thoroughly wet. The best plan of accomplishing this is to sprinkle it well with water from the fine rose of a garden watering pot. After the wetting, it is advisable to rear up the background for a time in order that the moisture may evenly diffuse itself in the fabric and also allow the excess of water, if any, to drain out. Next, the background is returned to its horizontal position, and the dry colour sifted over it from a fine sieve. When the surface is coated with a tolerably even layer of the pigment, it must be vigorously brushed into the canvas with a stiff brush, using a circular motion. The most convenient brush to employ for the purpose is an ordinary clothes brush with a handle. The great point to be attended to in this operation is to work the colour well into the canvas. The colour should be in the body of the fabrics, and not merely on the surface. When the colour has been well worked in, and the surface appears fairly even all over, the background is reared up and allowed to dry. It will then be finished. If by chance, when the background is dry, it appears uneven, the inequality arises from too little pigment being applied in the first instance. In this event the background must be rewetted, more colour sifted over, and the brushing-in repeated.

If a background with a graduated tint be desired, it is more easily produced by the powder process than by any other, all that is necessary in this case being to take some of the stock colour and make an addition to it of some more black, or white, according to requirement, then, by sifting on the different shades on such portions of the background as are required to be lighter or darker, and afterwards blending them in the brushing, the most perfect gradations may be secured. In all cases, in shading more particularly, it is essential that the brushing is done in a circular direction.

If a background, produced by this method, happens to get injured, say by abrasion or from water coming through the roof of the studio, the damage can be easily repaired. This is done as follows:—The background is placed on the floor

and evenly wetted as in the first instance. Then, after resting for a short time so that the colour and dextrine may become thoroughly moistened, the surface is gone over vigorously with the brush. After this treatment the background is reared up and allowed to dry, when it will be found restored to its original condition. In repairing an old background in this manner, the precaution should be taken that the whole of the adherent dust, if any, is removed before the water is applied.

WE are pleased to put on record a brief note we have received from Mr. M. Carey Lea, who, writing from Ashbourne, Pennsylvania, U.S.A., says:—"Your correspondent, 'E. V. E.,' who suffered from ophthalmia and 'nearly lost his eyesight,' should, if he returns to the practice of photography, be extremely careful of the sort of light he works by. This is far more likely to be the explanation than use of ammonia. Also should be careful about suddenly leaving the dark room and passing into a strong light. Two thicknesses of bright and deep yellow-green glass would suit for him, using gas behind them, not daylight."

SOME considerable portion of the correspondence columns of our contemporary the *English Mechanic* were recently devoted to the old question of the removal of silver stains from the hands. It is very singular that the one way of all others which succeeds the best should not be universally known, but it is yet true that the simple method of treating the stain, whether upon the hands or upon linen, with a solution of iodine, followed by a further treatment with solution of cyanide or of "hypo," even now is by no means commonly practised. It is true the hypo solution acts slowly, and that cyanide is objected to by many, but strong ammonia solution applied to the iodine-treated spot will almost instantly get rid of the brown stain, leaving in its place a slight greyish white, which would not be noticed; but it will not remove the silver stain as one writer states. Iodine, dissolved in water by the aid of iodide of potassium, is far cheaper and much better than "tincture of iodine."

THE old developing solutions, when used with silver solution, were the most fruitful causes of silver stains, but these were of a very different character from those brought about by contact with simple strong solutions of silver, such as that used for the printing bath, for instance. Once dried upon the hands these are by no means quickly removed.

STILL, nowadays, silver stains are so rare that they may be looked upon almost as things of the past; but, as every practical photographer is aware, pyro without silver brings stains of a very disagreeably persistent nature. They are, however, quickly removed by moistening the hands with a dilute solution of almost any acid—hydrochloric, nitric, oxalic, citric, &c. It must be observed, though, that after cleansing the hands in this manner they must be very freely washed in water, preferably hot, for if this precaution be not taken the stains will reappear under the use of soap and water.

THE long talked of Congress of Astronomers has become a reality, and the opening ceremony was a great success. The Congress, as our readers are aware, has been called together by the French Government to arrange a system for obtaining a photographic map of the heavens, and the plan has been greeted in the most enthusiastic manner by all eminent astronomers. The French Minister of Foreign Affairs addressed the gentlemen present at the opening ceremony, and spoke most strongly upon the importance of the subject. "You are," he said, "with a fruitful and cordial understanding about to arrange for the execution of a map of the sky whose exactitude will exceed not only everything hitherto achieved, but also everything one dared even to have dreamed of before the present day."

THE Congress soon set to work, Admiral Mouchez, Director of the Paris Observatory, being elected Honorary President, and Professor

O. von Struve, Acting President. A series of resolutions was passed, the first and last of which only we need quote. These were (1), "The progress realised in astronomical photography renders it absolutely necessary that the astronomers of the present century should undertake a conjoint photographic record of the heavens." (3 b), "To fix upon the best means to utilise at the present time the various data furnished by photographic processes."

With regard to processes of photography for this purpose, Admiral Mouchez in his late report gave some interesting data as to his experience with quick plates, and at the last meeting of the Royal Astronomical Society Mr. Gill, in his brief account of stellar work done at the Cape, made a very important announcement upon the subject. He had been using an English made plate of recognised great rapidity, but had been informed by Captain Abney that they could be replaced by plates of his invention which work eight times as rapidly. This is as great a gain upon the ordinary rapidity of dry plates as were dry plates upon wet collodion; it is therefore to be hoped that the new plates may be available for general work.

La Nature last week had a series of four excellent wood engravings from photographs of the moon taken by the Brothers Henry, and if they in any way resemble the original photographs they are a great advance upon previous work of the sort. Quick gelatine plates were used, and, although the moon photograph was of such size that if the whole surface were represented the map would be almost three-quarters of a yard across, the exposure given only reached a dozen seconds. The negative was taken with the aid of an eye-piece, as it was considered preferable to enlarge at the first operation rather than to first take a negative with the object glass alone and then enlarge it.

A NEW method of preparing gratings for light analysis was suggested by Mr. C. V. Boys at a recent meeting of the Physical Society. He found that some fine threads of spun glass and other substances he had made would, when placed side by side in the threads of fine screws, act like a diffraction grating and give banded spectra of white light. Mr. Boys's experimental results in the production of these fibres were most remarkable: he did not confine himself to glass, but tried melting and drawing out into these fine filaments quartz, sapphire, ruby, garnet, felspar, &c. With glass he was able to obtain fibres of less than the ten-thousandth of an inch thick; with quartz the marvellous fineness of less than the one-hundred-thousandth of an inch was attained, and these latter fibres were what he used for the diffraction grating. He obtained this exceedingly fine texture in his threads, not by the quick spinning of a wheel, but by melting the substances with an oxyhydrogen blowpipe, and then attaching a

portion to a straw arrow, which was then quickly shot out from a crossbow, leaving a trail of the delicate fibres behind.

PHOTOGRAPHIC INDUSTRIES.

THE PHOTOGRAPHIC FACTORY OF MESSRS. MARION & CO.

SITUATED in Chase Side, in the outskirts of the pretty northern suburban village of Southgate, is the new factory erected by Messrs. Marion & Co., of Soho-square, London, in which to carry on their various departments of a somewhat ramified business, so far as such departments embrace the preparation of sensitive plates, paper, and the many things which are cognate to these. The factory, although in full working operation and giving employment to numerous hands, can scarcely yet be said to have reached its ultimate state of completion, as at the time of our visit there were indications of its scope

being in course of still further extension.

The location is a very delightful one, overlooking a rich valley which separates Chase Side from Winchmore Hill, a tract of country now becoming closely studded over with the villas of London men of business, who, cooped up in their offices during the day, find the hygienic counteraction in the pure air of these northern slopes.

When we say that the Marion factory has been designed by Mr. Alexander Cowan, who is the resident manager, our readers will readily comprehend that it is just as perfectly adapted for its peculiar requirements as it is possible for

such a place to be. Everything had been so carefully thought out and planned, every end having its means so well adapted for it, that when the administrative services of architect and builder had been completed there was not found anything of which the wish could have been expressed that it had been otherwise.

On the occasion of a visit to this elegant factory one day last week, after entering the grounds we were first ushered into Mr. Cowan's sanctum, which partakes in some degree of library, laboratory, and plate-testing room—a species of *tria juncta in uno* place—which, by the way, consists of more than one room. As might be anticipated, we have here, almost by the wave of an imaginary wizard's wand, either full daylight, total darkness, or a flood of non-actinic light, at option. There are drawers in which plates, either singly or in the open box, may be temporarily stored away for consecutive testing by lights in convenient proximity, yet which when closed are actuated by automatic lid closers, by which the contents are safe even should the drawer be opened in strong light. In close proximity is the testing light, consisting of a gas flame in a recess with a reflecting shield so arranged as to prevent any light being transmitted by the yellow paper window in front save what is reflected from the back of the recess. Stability of illumination is thus ensured combined with

perfect safety. But when an exposure is to be made the front screen is withdrawn and the reflecting mask so rotated as to allow the direct gaslight to stream into the apartment. The utility of this was demonstrated in actual practice in course of our visit while some plates were being tested.

The plates are coated by hand. The operators sit at the end of tables on which, by systems of endless bands, each plate when coated and laid down is quietly removed out of sight in front. Subsequent investigation showed that this table is about forty-five feet in length, and that by the time each plate emerges from a species of tunnel at the far end the emulsion has set and the plate is in a position to be transferred to a framed rack which, when loaded, is conveyed into the drying rooms above. At the time of our visit arrangements were in progress to increase the output of the plates by adding more coating tables to those mentioned. As there is ample space at command there need be no limit to the coating capabilities of the establishment.

Proceeding to the room above, in which the plates are dried and in which, owing to the darkness, we had to grope our way by feeling rather than by seeing, we were made aware of the admirable system adopted for securing an ascending current of filtered air. This is done by a series of bent porcelain pipes let in through the wall at short intervals apart. The current admitted by these, after being filtered to ensure the absence of all dust, ascends through the drying racks and passes out at the top of the roof through apertures securely trapped to prevent the ingress of light.

The motive force is derived from a two-horse power gas engine, which, in addition to supplying all the power otherwise required in connection with the manufacture of plates, also drives the dynamo, situated in close contiguity, which furnishes the electricity for the lighting. The electric lighting system is supplemented by a storage battery, which proves the "friend in need" on any occasion when the engine has ceased running for the night. This storage battery will act for eight hours after the stoppage of the engine.

We inquired as to the means employed for packing the sensitive plates, and were shown large rolls of tissue-paper which were undergoing a species of baking to ensure the last traces of moisture being thoroughly eliminated.

The coppers (of which there are three) in which the emulsion is made are formed of porcelain. They are of large dimensions, and are set in galvanised jackets, the mechanical arrangements being such as to enable a steady heat being maintained at any desirable temperature.

One part of the factory is relegated to the preparation of albumenised and ready sensitised paper. This is lighted through yellow windows, which permits everything to be plainly seen without subjecting the paper to any harm. The paper is sensitised sheet by sheet, and is then directly transferred to the preservative solution, on which it is floated for a definite period, and thereafter suspended by clips on racks until dry, when each is subjected to a calendering operation, previous to being sent to the packing room in which they are put up for the market.

In another room we witnessed the operation of duplicating negatives, both indirect and reversed position, according to the method of printing to which they were to be applied. Carbon printing, both on paper and on opals, was here also being carried on, on quite a manufacturing scale, for, as our readers are doubtless well aware, Marion & Co. supply prints as well as the materials by which photographs are made. A Jubilee portrait of the Queen was the subject that was engrossing the attention of all hands when we were there, and it was being printed in a variety of sizes and by a variety of processes, both on opal and paper.

The factory, taken either as a whole or in detail, is singularly complete and well adapted for the various operations that are carried on. System, order, and method prevail throughout.

We give a view of the premises on previous page.

VARIATIONS IN "STRIPPERS."

I FIND no difficulty in cordially endorsing what I see in the first article of THE BRITISH JOURNAL OF PHOTOGRAPHY of April 8 regarding "the stripping film," and it was to my great regret that I had to slip away from the chair (where I only landed by an over-

sight of my own) at the London and Provincial Photographic Association meeting, when Mr. Wollaston was demonstrating, in his able and happy way, the processes employed in producing a stripping film negative. But during even the too short time I was present at the said meeting I managed to swallow and partly digest two things: first, a beef-steak, which is of no consequence now; second, the fact that great minds do not often run in exactly similar grooves. The leading article referred to corroborates the latter conclusion, and the two combined—Mr. Wollaston's demonstration and the leading article—cause me to write a few notes I have made during my now fairly extensive practice with the stripping films made by the Eastman Company. I am not going to write a bellicose article, for I agree with all that is found in the "leader," and Mr. Wollaston is in this particular line far too big a man for a little fellow like me to flout.

It has at times come to my knowledge that when a process has been in its infancy, rules too hard and fast have frequently deterred people from trying that process, the reason being either want of convenience, or time, or pluck, on the part of the would-be beginner, or else the stubbornness that has characterised our race ever since the days of that Biblical gentleman who was quite willing to bathe in any river except the particular spa recommended to him. My endeavour shall be to give such Naamans a choice of watering-places, and they can go in with their clothes on if they like, for one of the points of this process is that you do not need to "strip" unless you like. If, on developing a negative, you do not altogether fancy it, there is no necessity to proceed any further with it; it will make, perhaps, an ordinary paper negative, oiled or unoled, as wished. Or the negative, preferably unoled, may be dried and a print taken from it so that the qualities may be judged, and this is a greater advantage than some may think. Though I have, as I hinted above, considerable experience in stripping films, I cannot always be certain what sort of result I have got until I take a proof, and as collodion and "skins" are not to be had *gratis*, I can recommend this precaution to beginners when at all in doubt as to whether they have got a medal negative or a fit subject for the fire. The negative must not be aluminated, but well washed and dried. If a satisfactory print be the result, the negative must be thoroughly wetted once more, and can then be squeezed and stripped as if we had never doubted its excellence.

Mr. Wollaston was pretty emphatic in his preference for soda development over ammonia. I have developed with soda, potash, the two mixed, ferrous oxalate, ammonia, hydrokinone and potash, and other developers, and I greatly prefer ammonia and pyro to all the others. This is an old story. I have always preferred ammonia to other developers. Probably the variation lies in the man and not in the chemicals. I mention this not in contradiction to Mr. Wollaston, but to show that at all events it is a matter on which there are two opinions. If the films could only be developed to perfection with one developer, that would be a stone to heave at the process. Mr. Wollaston has produced splendid negatives with his soda, so have I with ammonia. Mr. Wollaston loves his soda, while "my heart is true to Poll," that is, ammonia. My only reason at present for my preference is a general one. Not long ago I had a particular reason, namely, that I had an idea that ammonia was less likely to cause insolubility of the substratum than soda when mixed with the tanning pyrogallol. Briefly, then, I may affirm that any developer which works well with gelatino-bromide plates will work equally well with these films.

I now pass on to other alternatives open to us in the stripping processes. The plate that is to carry the film after development and before stripping may be variously treated. The commonest and simplest and speediest method is to tale and collodionise the plate. But at certain times—for reasons I have not yet exactly run to ground—the film at a later stage has left the plate before I was quite ready for it. This is an important point sometimes, as for instance when the film, *minus* the paper, is intended to remain a long time or for ever on its glass support. In this case the plate should not be rubbed with tale, but coated with a thin solution of pure indiarubber in benzole, also pure, and then coated with collodion. A compromise which I always make now is to *edge* the plate with rubber solution after the tale and before the collodion. This was suggested to me by my friend Mr. Jackson, of the Eastman Company, and I find it most valuable. The film never springs prematurely, though when required it always rises to the occasion. The collodion I have always used is Mawson's enamel, but it is better to thin it with ether and alcohol (four ounces of the solvents in equal parts to one pint of the plain collodion). I see it sometimes recommended to add a small quantity of castor oil; I have had enough of that very valuable medicine, which may make collodion "tough," but has rather a different effect on me!

Anyhow, I have never used "ol. ric." in combination with collodion. This "talcum" and coating of glass plates might at times be inconvenient, but I find that the plates when coated with collodion, *if they are well washed* as soon as thoroughly set, may be dried off and stored away till required. I confess I was doubtful of this system until I tried it on a negative of no value which had itself been thoroughly dried. I made both the film negative and the collodionised plate thoroughly wet, squeegeed them together, and had no trouble whatever in stripping off the paper in water at the same temperature as I use for the ordinary routine of stripping work. But, (1), the solvents must be entirely washed out of the collodion as soon as it sets; (2), the paper film must be completely wetted before squeegeeing, and if any part of it had ever been dry it must *all* have been equally dry. The possibility of coating a lot of plates at a time and keeping them till required is valuable for the many who can only get chance moments for their photographic work. I do not recommend the system; I only state its feasibility.

I am sometimes asked if there is any advantage in having the water for stripping very hot, say up to 200°. I do not think there is any advantage in such hot water, nor have I ever found any harm to arise from it. So long as the water is hot enough to separate the paper in about two minutes I am quite happy. One of the drawbacks to the old process, before the collodion was introduced into the "new," as I call it, was that the water required to be very hot indeed, sometimes unbearably so. Nowadays my water is not usually over 120° Fahr.

After the paper either floats off or has been carefully removed, the film ought to be rubbed all over under the tap with either a broad camel-hair brush or the pads of the fingers. I prefer the latter, for if there is any grit or foreign matter on the film I feel it and beware, or remove it accordingly. But it is important to rub it somehow, in order to clear away stained pieces of the substratum. The alum and acid bath which follows this washing produces one of the most delightful changes with which I am acquainted. The plate goes in a leper and comes out an Adonis. Pear's soap and Madame Rachel are fools compared with the alum (saturated) and HCl (one ounce to about one gallon of alum solution).

Now I come to another variation in practice permissible with this process. The "skin," which as the leading article says is "composed of gelatine and glycerine," poured out upon a ground-glass surface, set, dried, and stripped, has two sides, one matt, the other smooth and shiny. If the matt surface is squeegeed next the film its mattness disappears; therefore, when my negative is hard I put the matt surface next the film. If my negative is thin I do the contrary, I leave the matt outside, and it acts like ground-glass. And the finished negative can be made hard or horny, or limp and flexible, according to the amount of glycerine put in the water in which the skin is soaked. The glycerine in the skin will dialyse out if the soaking water has no glycerine in it; this, of course, will result in a horny negative film. And *per contra*, a large quantity of glycerine in the water, especially in hot weather, will cause the stripped film to be limp. Here again we have a power of choice in the character of our finished film.

The skin need not be attached to the film at all until it is desired. The film may be dried on its glass support, may be printed from, or worked upon, or copied before the skin is attached to it. This I have repeatedly done. But before putting on the skin the film must, as before, be thoroughly wetted, else mischief will occur. This is another feasible but not advisable proceeding. There is no fear of failure if proper care be taken to wet both film and skin, but I have known cases where proper precautions have not been taken, "*hinc ille lacrymæ*."

After the skin and the film are quite dry, we have another series of alternatives. We may cut round the negative and strip it at once, or we may seal it hermetically between layers of collodion by coating the skin with collodion, allowing to dry, and then stripping. This I do with all my good negatives. I hear that professional gentlemen are afraid of negatives in this state, but were I of the number of professionals I should prefer these negatives sealed from dust and damp, unbreakable, not bulky, light, and beautiful, to any sort of glass plates. However, "Every man to his own gout."

The skin may be varnished with an ordinary negative varnish if wished. But if heat is required for the varnish then the plate originally must have either a coat or an edging of indiarubber, as the heat will cause the film to spring almost to a certainty. But while I have been writing this I have stripped a film collodionised on one side and varnished on the other, and on former occasions I have, with cold crystal varnish, coated both sides of films. This latter operation, however, requires some dexterity, as the film, when loose, is apt to rise and curl on the application of the varnish even if cold. I should like to know of something more durable, less heavy and bulky, less destructible, in fact, more satisfactory than one of these films.

It is true that the Eastman Company hold patents covering the manufacture of these films. It is just as well that some firm should command the manufacture, for the preparation of the films is a matter of very great difficulty, and requires very accurate machinery. And the very fact of such care being necessary makes our work all the more easy and certain when we do get the tissue, which getting of the tissue is perhaps the most difficult part of the process at present. I heard, not long ago, that I was a partner in the Eastman Company (!); I only wish I were, for I should either get a sufficient supply of strippers sent out, or else fire casual rounds out of a six-shooter, expense no object.

ANDREW PRINGLE.

A DEMONSTRATION IN PHOTO-MICROGRAPHY.

[A Communication to the Camera Club.]

WHEN invited to give a short communication before this Club, I felt that there was little that I could communicate which would prove serviceable to its members, and I was, therefore, reluctant on that account to accept the invitation; but, if what I have been enabled under many difficulties to accomplish, may lead others to take up a most fascinating branch of the photographic art, my appearance before you will not be attended by any regret on my part, and may be the means of adding to the enjoyment of others.

Having devoted myself for a great many years to microscopical pursuits, I have always felt the desirability of being able to keep reliable records of the various pathological and other biological tissues, when their characteristics seemed worthy of preservation.

Drawing these by the camera lucida, although quite possible and preferred by many histologists, seemed to me to entail such an amount of labour where there was much minute detail to be included, that I have always felt that could the aid of photography be enlisted there would be not only a great saving of labour and time, but the reliability of a photograph would be unquestioned and unquestionable. With this view, I set myself to construct the roughly made apparatus you see before you. First it was very simple, merely a box placed on its side and carrying my lamp, my object stage, and a microscopic objective, which acting the part of the lens in a lantern projected an image of the object on to a dry plate; but as I worked it I found it wanted various refinements and modifications, so it has been undergoing a process of gradual evolution, and various parts added as necessity demanded better adaptations. I now believe that as far as the principles of its construction go, it is as efficient as any apparatus for the purpose of photo-micrography need be. Its advantages are, first, its comparative cheapness—it might be constructed by any one with the aid of a carpenter; secondly, it can give any sized photograph, from a lantern size to a 34 × 48 plate—I content myself with any plate up to a 7½ × 5; thirdly, it gives a field of view limited only by the size of the plate without the constricted circle produced by the microscope tube; fourthly, beyond its capabilities as a photo-micrographic camera, it can be used as a projection microscope, a magnified image being easily thrown and clearly seen on a four-feet screen. I need not take up the time of the meeting by any description of the apparatus, as it is before you, and you can see for yourselves, and detailed descriptions of it have appeared in the photographic journals;* its method of employment I shall have the pleasure of showing you further on. I may only say that two useful additions have been made to it since the last description was published. The sliding baseboard, carrying the printing frame, and, which in using, holds the sensitive plate, is stopped every half foot by a bolt which passes into its side and keeps it fixed, an object of a known diameter, say, one-sixteenth of an inch, is projected on to the plate at each division—the measure of its magnified image gives the number of diameters it is amplified. This must be done for every objective employed, and a table constructed for reference. Such a table for the objectives I use is now before you.

There are difficulties attendant on the practice of the art, not arising from this apparatus, but from the nature of the subjects submitted to its action—I mean the character of the preparations to be photographed, and, perhaps, by pointing these out some remedy may be found through the aid of those who prepare objects. I presume there would be no objection to retaining such mounted subjects as are now prepared to view with a binocular microscope, where depth or thickness rather adds to than takes from the utility of a preparation, but where it is desired to obtain a photograph, the greatest thinness of a section compatible with keeping the structure together should be sought after; this in conjunction with a suitable stain would enable a good photograph full of detail to be obtained.

* The details of construction will be found on page 149 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1887.

The staining should be of an uniform tint, not stained with a selective stain, for however interesting it may be to the histologist to see the nuclei of a tissue brought out, it does not improve the appearance of a photograph to see it dotted all over with these spots; moreover, they mask the true histological detail, which is the more important element. The colours most favourable towards the attainment of a good result are worthy of consideration. Red staining by carmine is very suitable if not selective or too deep; a pale stain from a diluted solution of Bismarck brown gives a satisfactory photograph; eosine stained preparations work fairly well, as do iodine green; but a pale blue or lavender makes the exposure so rapid that at present I have not succeeded well with preparations stained with them.

But whatever the colour of the preparation, it is absolutely necessary that it should be thin and mounted perfectly flat all over, or a decent looking photograph cannot be obtained. The proper time of exposure can only be ascertained from experiment. The light employed should be as uniform in quality and quantity as possible, and that from a paraffine lamp with a half-inch wick is ample if the edge of the wick is just slightly turned away from the object. The light may be intensified and made more actinic by putting a piece of camphor, the size of an ordinary walnut, into the reservoir containing the paraffine; this whitens the light and a perceptible difference is made in the exposure by its omission. Treating of the light brings me to the mention of the latest addition to my "bantling," as some one rudely called it. I found the light so superabundant that all the details of my preparations were flooded, therefore I devised an addition by which I can graduate the light to suit the details of the subject. I accomplish this by a tube fixed to the back of the object carrier, and in which a short piece of tube carrying a stop is moved backwards or forwards till the exact amount of light is obtained, and the effect of which I will show you presently. I hope I have said enough in this short communication to introduce the "bantling," and I will now proceed to show how I use it. My album of photo-micrographs on the table will, I flatter myself, sufficiently testify to the efficiency of the apparatus.

I have not brought any very difficult subjects to photograph, as I merely wished to show you the *modus operandi*, and difficult subjects take a long time to illuminate properly, but I have brought the tongue of the blowfly—a very fair test, a section of *Psamma arenaria*, and a section of Echinus spine, all of which give very satisfactory results, especially with a one-inch objective. T. CHARTERS WHITE.

PHOTOGRAPHY AND BOOK ILLUSTRATION.

[A Communication to the Glasgow Photographic Association.]

DOUBTLESS, when you saw that I was going to give a paper on *Photography and Book Illustration* this evening, you would think me a very rash individual indeed who would attempt in one single paper to go over all the ground that is implied in the title, "Photography and Book Illustration." No one can have a keener appreciation than myself of what is required to do justice to the subject chosen. I intend, however, to bring before you this evening only what has been done in one particular direction. I refer to the part the silver print has played in the illustrating of books. I say "has played" advisedly, for it is clear to demonstration, tested as it has been by actual experience, that the silver print, as far as book illustration is concerned, can have no future before it. Photography can and does still lend its helping hand, but in another way. It will be quite beyond my province this evening to trace what may be called its development in this direction. Nothing could be more interesting or more enticing than to show how collotype or lichtdruck printing was introduced to supersede the beautiful but evanescent sun-printed image, to refer to the photo-mechanical processes of Woodbury, to speak of photo-engraving processes, or to discourse on the possibilities opened up by the employment of the comparatively recent sensitive papers, the bromide and the Alpha. In addition, we would have to consider the processes brought forward by various experimenters having for their object the production of a photographic block that can be used for purposes of illustration along with the letterpress, one printing operation sufficing for both. Clearly the consideration of all these expedients would entail much more time than is accorded at a single meeting. At some future time, provided it would interest the members, and other material not coming forward, I would be very glad indeed to take up this important and somewhat extended subject at the point where we will leave off to-night, treating the various branches of it in the order in which they appeared, and illustrating this or that particular process by actual specimens of the finished production, much in the same way as I purpose treating to-night this matter of the silver print and its relation to the illustrating of books.

I am not aware whether the particular phase of book collecting that is being brought under your notice this evening has to any extent been carried out by other book collectors. Interested in books and, as you are aware, interested in photography, what more natural than that a sort of bias should be displayed in getting together a collection bearing somewhat on the history of book illustration so far as it has been assisted by means of photography. Talbot, judging from some of his remarks to be found in his introduction to *The Pencil of Nature*, evidently thought that there was to be a great future for the sun-printed image in the way of illustrating books. Talbot was a man who evidently had the courage of his opinions, and as the result he published the two books, *Sun Pictures in Scotland* and *The Pencil of Nature*. As you recently had an opportunity of seeing my copy of the former work, I need not enter into detail regarding it. It, however, lies on the table for the inspection of any one interested. I have not yet been able to secure a copy of *The Pencil of Nature*, but I do not despair. I hope yet, some way or somehow, to become the happy possessor of the volume in question. We may take it, then, that the two works in question were the first in this or any other country to be sent forth to the world enriched with veritable photographs.

In 1846 the *Art Union Journal* published, as a supplement, a specimen of Talbot's calotype. These prints were produced from various negatives, so that we should find (were it at all likely the opportunity presented itself) that on comparing the different issues a considerable variety existed in the prints published. I have endeavoured to get a look at some of these early productions, but not a single public library in Glasgow possesses a copy of the *Art Journal* for the year 1846. My object in thus hunting up the matter, so to speak, will be apparent when I come to speak of the paper negatives, said to be Talbot's, which have been brought in to-night for purposes of exhibition. I was, and am, naturally anxious to identify the negatives, so that if I came across a print corresponding to any one of the negatives the assumption that all the negatives are Talbot's would be a reasonable one. This Talbotype which you see here, and which I have been informed represents a street view in the town of Frome, is in a volume of the *Art Journal* which belongs to our worthy member, Mr. Andrew Maclear, and we have to thank him for letting us have a look at this picture with its forty-one years of existence. I may mention that I saw recently another of these *Art Journal* Talbotypes. A Glasgow gentleman who possesses a complete set was good enough to let me have the volume for 1846; and the picture in his book for that year also represented a street scene, but it was very much smaller in size (about a quarter-plate) than Mr. Maclear's one. In addition to these I have been fortunate enough to secure this single number of the *Art Journal* containing the supplement. For a year or two back I had been on the outlook for either the volume or the number, and this very week I have succeeded in getting what I have been waiting for. The picture in the number now brought under your notice is totally different from those already indicated to you—it represents a scene on board some vessel. It is most unfortunate that we have no means of knowing what the original subject was.

I have been informed that in an early number of the *Glasgow Mechanics' Magazine* there is to be found one of these Talbotypes, also issued in supplemental form, but this I have never seen.

The first scientific journal in this country to be illustrated by means of the silver print was the *Quarterly Journal of Microscopical Science*. The print which you see here was published in 1853, and appeared in the April number of the *Journal* for that year. Although somewhat faded it is still in good preservation. The negative was taken by Mr. Delves to illustrate a paper by Mr. Shadbolt, a former Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*, and the subjects represented are the spiracles and tracheae of silkworm and proboscis of fly.

Let me now call your attention to this small volume here, known technically as a 12mo. It is an edition of Virgil's complete works. Our interest in it lies in the fact that the work has been profusely illustrated with small silver prints. These we find forming head-pieces to the various books of the *Aeneid*, &c. Judging from the appearance of the prints I would be induced to say that they had been sulphur toned in the first instance. The pictures themselves are from studies of the antique. I understand that the publishers of this volume, Firmin-Didot of Paris, also published an edition of Horace's works illustrated in the same way as the Virgil now before you. These volumes were, at their date of issue, somewhat high priced. I regret I have not the Horace to show you, nor have I seen it. The date of publication of the Virgil is 1858.

The large volume here should have a special interest to the members of the Glasgow Photographic Association. It is a work published by Collins of this town, and is entitled *Palestine in 1860*. The letterpress is by the late Rev. Dr. Buchanan, and the views shown,

twenty-four in number, were taken by a quondam member of this Association, Mr. John Cramb. The prints are all in excellent preservation, testifying to the original good character of the work produced. I have not much information regarding the negatives from which these prints have been produced further than that they were taken on plates prepared by the albumen process.

Mr. Cramb contributed a series of articles to THE BRITISH JOURNAL OF PHOTOGRAPHY detailing his experiences while sojourning in the Holy Land. The articles in question commenced in the number of the JOURNAL for December 1, 1860, and were continued at intervals during the various months of 1861. To the past generation of photographers Frith's photographs were well known. I have here a copy of a work embellished with Frith's handiwork, and it, like Cramb's, presents to us the leading characteristics of the Fatherland of the Jews. The publication of this book, which has for its title, *Sinai and Palestine*, is also due to the enterprise of a Glasgow firm, namely, Wm. Mackenzie. The photographs were taken in the year 1857, thirty years ago, so that in point of time they are three years older than those of Cramb's. Judging from their appearance I would say the prints produced by Frith had been more heavily toned with gold than Cramb's pictures had been, and the preservation which has attended them is without doubt due to this circumstance. The photographs are thirty-seven in number, and, apart from the interest of the places shown, are in themselves highly artistic.

Passing from these, let me call your attention to this volume, which should have an especial interest to us. To the members of any Glasgow Society the name of Hugh Macdonald possesses a certain charm. I presume that there is no one here unacquainted with this author's *Rambles Round Glasgow*, and *Days at the Coast*; should, however, there be such an one, and he a Glasgow man, let him hasten to remove the reproach by procuring the works in question, and I am sure he will not be disappointed when he comes to peruse their contents. I was quite unaware, till recently, that editions of Macdonald's works had been published with photographs of the places referred to, and I regret I am as yet only able to show one of the works, namely, *Days at the Coast*. The book was issued by Andrew Duthie, of Gordon-street. Throughout the book will be found twelve photographs, the work of Mr. T. Annan. There is no date of publication attached, but I am in a position to fix the date as about the year 1868. This work here, entitled *The Old College*, being the Glasgow University album for 1869, next claims our attention. You will find therein two photographs, one of the old entrance to the College when it had its home in the High-street, the other giving a representation of the present edifice as it appeared in the year 1869, surrounded with scaffolding, and, as you will see, before the main central tower had begun to show itself. This print is, undoubtedly, a silver production; I am not so sure of the other one. I leave it to some of the members to say whether or not it is, as I think it is, a Woodbury-type. In connection with this matter of the illustrating of books by means of the silver print, there is one firm in Glasgow that has done a good deal in this way—I refer to Messrs. Annan—and through their kindness I am enabled to bring before you several volumes which as yet do not form part of my own collection. Messrs. Maclellan, several years ago (1870) published a work entitled *Old Country Houses of the Old Glasgow Gentry*, and this is the book in question. The first edition differs from the second in this, and that is what concerns us most, that the photographs were all silver prints in the former, and in the latter recourse was had to carbon. It is a book that has gone up very much in price—published originally at five guineas, the price now asked by the publishers is ten guineas.

Messrs. Annan have also reproduced in book form the works of Sir George Harvey and Sir Henry Raeburn.

Here are the works referred to.

Many of our members may remember a loan collection of pictures that was held in the Corporation Galleries in 1869. An interesting memento of the more prominent pictures then exhibited will be found in the thick volume lying on the table; it is the catalogue of the complete collection interspersed throughout with silver prints.

Here is yet another book to which the Messrs. Annan have contributed the illustrations, entitled, *A History of the County of Bute*. The work is by Mr. John Eaton Reid; a son, I understand, of Senex Murray was the publisher, and we find throughout the work nine photographs of the principal places of interest on the island. The date of publication is 1864. Curiously enough, I have just been informed by Messrs. Annan that so recently as 1885 they prepared silver prints to illustrate a book published by Paterson of Edinburgh, *Castles and Mansions of Ayrshire*, and prints to the number of seventy are to be found in this work. I think this must be a case of the exception proving the rule when we stated that the silver print had no future before it in the way of book illustration. Very many other

works have been illustrated by Annan, but, as they have been done by carbon, we pass them over on this occasion. It is but fair to state, with reference to the illustrations in the last-named work, that it was solely at the publishers' desire the silver prints were inserted. Messrs. Annan would have preferred either carbon or photogravure.

Wilson's *Photographs of Scotch Scenery* are known to all of us. Could more appropriate illustrations be found for a work such as Scott's *Lady of the Lake*? This edition of Scott's famous poem contains eleven photographs by Wilson of the more picturesque spots now made famous by the master-hand of our great Wizard of the North. The edition we are considering was published by Messrs. A. & G. Black, of Edinburgh, in 1869. It is bound in a somewhat unusual manner; the boards are either of wood or *papier maché*, I am not sure which, and the whole has been covered with, I think, a coloured paper representative of tartan, and which has received a coat or two of varnish. In addition two photographs have been laid down on the covers, one representing Sir Walter himself, the other his monument in Princes-street, Edinburgh; these also have received their protecting covering of varnish. The freshness of these two outside pictures is remarkable when compared with the prints in the body of the work; in fact they show less symptoms of decay, and that notwithstanding the fact that they have been exposed to light and friction for a period of close on twenty years.

This book on *Staffa and Iona*, published by A. Marion, Son, & Co., London, in 1867, contains twelve photographs all emanating from the studio of George Wilson, Aberdeen.

In this work, entitled *The Great Works of Raphael*, and published by Bell & Daldy, London, in 1867, there will be found twenty silver prints. It is to be noted that the negatives in the first instance have been taken not from the original oil paintings by Raphael, but from what have been regarded as the best engravings of these masterpieces. In this other volume, also published by Bell & Daldy, the same course has been followed, the engravings of the artist's works have been photographed and not the actual pictures themselves. Of course we are dealing with a period when the isochromatic plate was unthought of, or, perhaps, if not unthought of, at all events it was not *un fait accompli*. The artist's works herein represented are those of Sir Edwin Landseer and the book contains sixteen photographs of his early works. The year of publication is 1869.

Here is another edition of *The Lady of the Lake*, one published by A. W. Bennett, London, in 1863. A companion volume published by Bennett will engage our attention a little further on. The photographs illustrating the book are fourteen in number, and with the exception of the frontispiece, by Wilson, of Aberdeen, are all by T. Ogle. Many of the views are very fine, having been taken from points of view not generally selected. Bennett seems to have been a publisher who believed in employing photography as a means of rendering his books attractive. This work, *A Walking Tour in Brittany*, by I. M. Jephson, was sold along with a set of photographs (stereoscopic views) illustrative of places visited, and there is embodied in the work a series of photographic notes by Lovell Reeve, I presume the naturalist of that name. I have not these views, but there is as frontispiece a photographic representation of a street view of some town in Brittany; date of publications, 1866.

Here is a volume published in 1862. It is an edition of William and Mary Howitt's *Ruined Abbeys and Castles of Great Britain*, having throughout the work a series of some twenty-seven photographs of a somewhat small size. The prints have had spaces left for them in the letterpress, and have been affixed, I presume, after the binding of the book had been completed. The photographs are all in very excellent preservation; they are by various contributors, Bedford, Sedgfield, Wilson, Fenton, and others. The publisher of this edition is A. W. Bennett, London. I would beg to call your attention to the condition of two photographs that have been put on the outside covers of the book, much in the same way as those outside pictures already referred to in the edition of Scott's *Lady of the Lake*, only with this difference, there evidently has been no protecting varnish. While those on the outside of Scott's volume have suffered little or no change, those on the present volume are almost wholly obliterated. There would appear, therefore, to be something in the use of a varnish after all to protect a photograph. Take, for instance, the case of those photographs that are laid down on the wooden articles that come from Mauchline; they stand for years and no signs of fading will be appreciable.

A recently published volume, with silver prints for illustrations, is the one which I have here, and which hails from America; its title, *A Trip to Mexico*, and the author, H. C. Becher. As the date of issue was 1880, we would scarcely expect to find symptoms of degradation already. It contains six photographs, and the publishers are Willing & Williamson, of Toronto.

This, gentlemen, completes the list of the books illustrated by means of the silver print which I have brought here for your inspection this evening. While I cannot claim that the collection I have so far got together represents anything like the actual number of books that have from time to time been issued with photographic illustrations, still I have managed to secure a few things that perhaps may be well reckoned unique. It will be readily understood that books of the class I have been this evening considering are only obtainable now and then, at auction sales or second-hand book shops. A good deal of time is therefore required for the necessary hunting up of the material, and, after all, very often the thing sought for is not obtained.

WILLIAM LANG, JUN., F.C.S.

SULPHURATION OF PRINTS.

PERMANENT SENSITISED PAPER.

To judge from what one sees in our journals of late, one would think that the days of albumenised paper are over, and that the only question remaining to be decided is, Which of the new processes that are in turn being lauded up to the skies is to be the printing process of the future?

I know many of my photographic friends do not consider me to be conservative in my photographic ideas as a rule, but somehow I cannot help thinking that our old friend albumenised paper will live to see daylight through our negatives for many a year yet, even though many negatives may be poor, thin, yellow ones which do not give him a fair chance to show what even he is capable of in regard to permanence.

I would advise an amateur who thinks any child can do the printing, and who puts his printing frames out until the high lights on the paper are just beginning to tint, and then thinks all has been done that can be, to use the modern processes, as the results will last longer.

But it is the experienced printer and amateurs with artistic taste who soon find out how impossible it is to get equal results with these blind processes that they can with the old printing out ones. I have just been looking through a number of prints done by one of the most experienced workers in England in one of these development processes, and I feel convinced that there is hardly one of those prints in which he would not have deepened a shadow or slightly tinted a too obtrusive high light, could he only have seen and had the power of doing just sufficient and no more.

Platinotype, for instance, does capitally for representation of bas-reliefs and such like, and even for portraits when there is an experienced operator who knows how to build up a picture round the figure with the aid of suitable background and accessories. But with landscape work we very, very seldom come across a negative perfect in its balance of light and shade, and which does not require a little dodging to make a picture of it.

Let me be understood. If I came across one of these very rare specimens of a negative, I would most certainly print it in one of the more permanent processes; but from the negatives which I, for one, produce, in nine-tenths of them there would be some point which would be an eyesore every time I looked at it, so until we obtain a *printing out* process of more permanence, I intend to keep to our old friend albumenised paper for general work.

These are the reasons for my experiments to endeavour to discover the probable comparative permanence of ready sensitised paper with that freshly sensitised. For my tests I obtained a few prints on freshly sensitised paper from a gentleman who is acknowledged to be an authority on everything connected with silver printing. I might add that they were printed on Trapp's albumenised paper.

The permanent sensitised paper prints I produced myself on a paper in the market which is as good as any I have tried. Further, I was aware of a few particulars as to its production; that is, I knew that chloride of ammonium was the salt and citric acid the preservative used. I first obtained from the maker of my sensitised paper a sheet of the paper before it was albumenised, because I wanted to find out, as it was a very pure white, whether it contained any sulphides (such as ultramarine, sometimes used to disguise a slight yellow tint) which might have a bearing on the result. I tried the acetate of lead test, and could find no trace of any sulphide. I then selected my prints on the permanent sensitised paper, toned to as nearly as possible the same colour, and printed to the same depth, as the prints on fresh sensitised paper I intended to test them against. I also added a number of other prints, printed from thin and dense negatives and toned to different tints. Also pieces of albumenised paper (both fresh and permanent sensitised) which had not been exposed to daylight, but which had been passed through the toning and fixing baths with the prints; and, lastly, I added a piece of the plain paper before albumenising.

My first test was to see how these prints, &c., would stand against a prolonged exposure to a sulphuretted atmosphere. I did not consider it would be hardly fair to test the action of a solution of sulphuretted hydrogen upon them, as the conditions would not be similar to prints exposed to an ordinary atmosphere contaminated with only minute traces of the gas.

I therefore took a large glass bottle, to the cork of which I suspended a piece of sponge full of water, the prints, &c., were put in, and the cork sealed, through which passed a glass tube from a bottle containing sulphide of iron and dilute sulphuric acid.

At the end of a week I examined the prints, which showed the following results.

The paper which had not been albumenised was unchanged in colour, showing there could be no discolouration due to anything in the paper. The sensitised papers of both kinds not exposed to daylight, but which had been passed through the toning and fixing baths and thoroughly washed, had yellowed considerably, and as near as I can see, equally, showing that albumenised papers which have had free nitrate of silver in them are acted upon irrespective of the action of sulphuretted hydrogen upon the silver image reduced by light. The importance of this point will be seen better when I come to the question of the bromide papers.

In the comparative prints of equal tone and depth of printing, the half tones and shadows were faded nearly equally, some of the fresh albumenised paper prints, if anything, getting the best of it.

I was rather struck with one point, however, and that was that in both cases prints toned to a purple tone seemed to have yellowed more in the lights and half tones than the prints of rather warmer colour, which almost seems to show that, beyond a certain point in toning, the gold produces an injurious action upon the prints. Indeed, I was surprised to see how well prints from good bright negatives stood when only toned to a very warm tone, or even of a so called foxy tone, compared with prints of a purplish black colour.

The appearance of the whole of the prints pointed to one important fact, and that was that the character of the negative is of far greater importance as regards permanence than the colour given by the toning to the print; and I am very much afraid that prints from average negatives produced on the rapid dry plates at the present time will stand a poor chance of permanence when compared to prints from the old wet plate negatives with their clear glass and dense image.

Even the shadows in the prints from fairly bright negatives, which seemed to the eye to be as dark as in the prints from the more dense negatives, the sulphuretted hydrogen soon showed the difference, as far as the destruction of the image was concerned.

As for the prints from the thin negatives, they were destroyed to such an extent that I would seriously advise all photographers who print on albumenised paper, in every case where it is possible, to eschew the rapid plates giving these thin images; indeed, with some makes of even slow plates in the market it seems almost impossible to get a dense image with anything approaching clear glass on the same negative.

The density of an image does not depend upon the amount of silver in the film, but on the way the emulsion is prepared. The densest and best negatives I have ever produced have been with only six grains of silver nitrate to an ounce of emulsion, and the thinnest with over twenty grains, so that if one *cannot* get dense negatives on properly exposed plates with a certain brand of plates I feel convinced that the fault is in their manufacture. Of course I am not now referring to thin negatives due to errors in development.

HERBERT S. STARNES.

CONTINENTAL PHOTOGRAPHY.

DILATING OR SHRINKING GELATINE FILMS.

M. LECORNEY has experimented upon stripping gelatine emulsion films, and enlarging or diminishing them to a required size; he used commercial plates, which do not all give the same results. The plates of M. Bernaert after being developed with ferrous oxalate, and again wetted with the developer, will part with their films when the plates are held at an angle and the films pushed with the finger, but if they be at all washed first this is not possible. When well expanded after the separation, they can be alumed and fixed in the ordinary way. With the plates of M. Lumière, also those of M. Bacard, other means must be adopted. After their removal from the iron bath they should either not be washed or be but very slightly washed, for it is necessary that a little iron salt should remain in the film; then they must be dried in the dark. Once dry, it is but necessary to plunge the plates of M. Lumière into water, and the films

will come off of themselves. With the plates of M. Bacard it is necessary to make gentle use of the finger after the washing. As in this case the film sometimes folds over itself, it is good to cover it in advance with some neutral powder which will prevent adherence of the folded parts.

It is possible, as is well known, to deal with all makes of plates by means of a strong bath of alum to which citric acid has been added, but the operation is rendered much more easy if the film be allowed to dry before using the alum bath. When the separated films are much dilated, they become so thin that it is difficult to manipulate them. M. Lecorney overcomes this difficulty by covering them with a solution of plain gelatine, after which they are dried, then submitted to the treatment already described. The acid bath dilates the film; it can be shrunk with an alkaline bath, and thus it is easy to get any desired dimensions.

Lastly, M. Lecorney calls attention to a curious fact. It is known that sulphocyanide of potassium dissolves gelatine freely, so he thought that the addition of a little of the sulphocyanide to water, acidulated with sulphuric acid, would favour the expansion of the film, but to his great surprise he found that it produced the contrary effect—the image contracted in such a fashion that it was reduced to but a third of its original dimensions. Simple washing undid the action of the sulphocyanide. Here then is a new field for experiment.—*Bulletin de la Société Française de Photographie*.

SILVERING GLASS.*

M. H. Bory states that the glass to be silvered should be carefully cleaned, then levelled horizontally in a situation in which it is kept heated to a temperature of from 25° C. to 30° C. If the temperature is lower the metal will precipitate but slowly, the deposit will be incomplete, and the silvering bad.

Solution A.

Distilled water 1 litre.
Rochelle salt (tartrate of potash and soda) 10 grammes.

Put the Rochelle salt in a porcelain evaporating basin with about 250 c.c. of the water, and add to it about 0.5 gramme of nitrate of silver. Heat it to nearly boiling point, by which time all should be dissolved. Add the rest of the water, pour the whole into a beaker, and filter.

Solution B.

Fused nitrate of silver 5 grammes.
Pure ammonia 3 „
Distilled water 1 litre.

Add the nitrate of silver to the ammonia, stirring until almost complete solution has been effected, then add the water and filter. At the moment when required for use, mix sufficient of equal parts of the two solutions by pouring them backwards and forwards from two vessels, after which pour a little of the mixture upon the glass, and distribute it evenly over its surface by means of a piece of chamois leather. Immediately afterwards pour on the rest of the mixture so that it shall well cover the glass without spilling over its sides.

After the lapse of thirty or forty minutes at the most, the silver is precipitated in the metallic state and adheres firmly to the glass; the liquid is then poured off, the deposited surface is gently sponged, rinsed with a little water, the glass placed on end to drain, and when it is dry the back is painted over with varnish or other preservative coating.

To avoid spots and an uneven coating it is indispensable to use absolutely pure distilled water. The argentiferous waste solutions should be saved and the silver in them recovered. When a thicker silvered surface is desired the foregoing operation can be repeated upon the same piece of glass. The vessels used in these operations should always be washed with distilled water.—*Bulletin de la Société Française*.

THE DEATH OF LÉONCE ROMMELAERE.

Sad news reached us a few days ago of the premature death of M. Léonce Rommelaere, Director of the Industrial School of Brussels, and first General Secretary of the Belgian Photographic Association. Letters making known this much-to-be-regretted loss to photographic science have been addressed to all the *savans* of photography and to the photographic Press by the thoughtfulness and in the name of the Belgian Photographic Association, which bears testimony to the great skill and devotion of our lamented brother. We feel strongly the regrets which inspire our colleagues in Belgium at the death of so distinguished a man, who was of an age which should have enabled him had he lived to render numerous other good services to our science.—*Le Moniteur de la Photographie*.

* This is much the same process as that described in these pages about twenty years ago by Mr. Carey Lea, but M. Bory gives in addition minute details for avoiding uneven deposit and spots, which are the chief difficulties in silvering glass.—TRANSLATOR.

WHERE I WENT WITH THE CAMERA.

NO. IV.—RHEDEN AND SCHERPENHOFF.

On the road to Rheden the avenues of beech-trees that stretch along the highway for miles and miles are delightfully imposing. Trees planted close together, straight as arrows, tall as spires, majestic as the pillars of a temple, grow up on either side of the carriage-way as far as the eye can reach; then a footpath on either side with another row of trees running along the outside of each of these, make four rows of trees in all. To reserve the footpaths for pedestrians only, trees are planted at intervals in the centre of the walking-way, so that neither horse nor vehicle of any kind can get along.

A great boon to the traveller these limitless arches of green must be—a shelter in stormy weather from the violence of the wind and the rain, a cool shade in the summer from the heat and glare of the burning sun. When walking through these avenues I came across many knots of children sweeping up the *débris* on the ground around the trees and filling bags with it. On investigating the matter, I found that it was the beech nuts that had dropped from the trees they were sweeping up. The little people were out making their harvest, for they took the bags when full and sold them to traders, who paid them so much a bag for them.

When in this district I stayed at Scherpenhoff, a family mansion-house on the borders of the Ysel; it was built in 1699, and time has not traced a furrow on its front. It lies embedded in the midst of interesting scenery close to a river, surrounded by trees, and inhabited by most genial and loving friends. I said, here let me strike my tent and rest awhile; which I did. I reached Scherpenhoff after dark; out of the night and the shadow of the trees my conveyance drew up at the hall door, which, standing open, threw a cheery light across the path, the lamps within playing upon smiling faces that beamed the welcome that merry voices in full chorus greeted me with as I entered. Beyond, the dining-room door stood open and inviting, table spread with snowy cloth and all things ready. A cheering sight for a hungry guest.

I was rather partial to the general fare in Holland. Many of the dishes were quite new to me, and highly enjoyable. I liked the times at which the meals were served. In some parts I believe these vary, but where I visited we got in the morning coffee and some light eating. The black bread one has heard so much about was served at this meal in thin wafer slices, daintily cut, and placed upon the white bread and butter, a sort of luxury rather than common food, talked of as to be looked upon with suspicion. We breakfasted from half-past twelve to one o'clock, solid meals served much as a good lunch would be at home. Dinner at six o'clock. Everything is served in separate courses. Between the soups, meats, and *entrées*, vegetables were served as separate courses, tastefully cooked, seasoned, and sauced, and very delicious many of them were—endive, cabbage, celery, &c. I also like the leisure and quiet comfort with which everything was done. After fruit you enjoy your cigar, whilst the lady of the house has a brazier introduced. This is like a metal pail, filled with hot embers, on which a bright, steaming little kettle goes on singing its song (Watts's hymn I suppose you would call it). From this apparatus, which is placed by the hostess's side, tea is made and served out as long as you like to sit and drink it, that same time in many cases being pretty considerable, as we sat and talked and played cards and drank tea. The ladies turned to their fancy work, and their jokes were cracked, gossip talked, and little plans arranged, all under the influence of tea.

I was at Scherpenhoff taken in charge by two young ladies, aged respectively thirteen and fifteen, who trotted me all over the place and made me photograph anything and everything we came across. Then I had to develop a plate or two to show them how it was done and what they were like. Next a print or two were demanded. You know what despots children are, and how insatiable is their thirst for knowledge. To show how the negatives would turn out in the way of printing, I had to go back to Arnheim to beg a piece of sensitised paper from a photographer there. Then, having no toning solution, I fixed them in hypo and washed them. Only people living away from the busy haunts of men can have any idea of how those girls treasured the yellow looking impressions I made; they seemed to look upon them as art treasures. Nina and Nellie were my little friends' names. Nellie wanted the mule done, and Nina would bring the retriever; Nellie would propose the fowls, and Nina would pose the pug, &c. So we had a lively time of it for a day or two, I can tell you.

The old house and its surroundings were picturesque and interesting, and I got some good pictures of them. It looked the ghost-story sort of place, quiet and secluded. None of the villagers would come near it after dark. They had seen something, of course; very likely the man going to the stable with a lighted lantern at midnight, or a reflection thrown upon the trees from a stained-glass window, or some other such weird spectacle. No matter, they had seen it, and they would not come near the place at night.

I visited and photographed most of the castles in the immediate neighbourhood. Every man's house is his castle here. Of special note was the Castle of Rosendall, the grounds of which were very beautiful, but I found the mansion-house itself more peculiar than pretty. New gables joined to a keep hundreds of years old, all rising out of the water (with which it was surrounded), was barren of pictorial effect from any point of view. But the Count van Palland, the proprietor, certainly

makes up in his grounds for the lack of beauty in his house, for they were a perfectly charming combination of wood, rivulet, and lake, and the Count is not above giving the visitor to his domain a little pleasure, or pain, as the case might be. He has a swinging bridge fitted across a small stream, that if you venture on you must rush across from the one end to the other, for if you hesitate in the least you are lost, that is to say, you will fall on your nose in the middle of it. I saw them do it—"both ways." I did not try it myself. If I had broken my nose it would have been awkward. In another part of the grounds, where the view of the castle is supposed to be finest, there is concealed a pipe and tap. The initiated, whilst you are absorbed by the view, turn on the tap, when a thousand hidden jets in the ground all around send forth a volume of water which is somewhat astonishing and very wetting. It depends on the humour one is in whether it be pleasant or not. But they didn't have me.

Middachten was another castle I visited. It belongs to the Bentinck family. It also is surrounded by water, but it is a very old house and more picturesque, a better subject for photography than Rosendall. The miles on miles of beech avenues that surround it on all sides is in itself a wonder well worth going a long way to see.

I spent a day in the village of Rheden amongst the white-haired, elg-footed, ponderous moving children, who can smile and laugh and tumble about withal, but their very playfulness seeming the business of effort. Under those pates of bleached, tufty hair, and behind those soft, sleepy-looking blue eyes, where lie hid the embers of future manhood and womanhood, who can say what fires of daring and doing may not be smouldering? For has not this little country of about one hundred miles long by fifty wide produced in its time genius, heroism, and courage, out of all proportion to its size, with its Rembrandt and Hobbema, its Van Tromp and De Ruyter? And what has been may come again. But surely their progress must be a solid, slow walk to success if movement means anything. They could never rush to glory.

All around this district the great and placid amusement of the peasant on the Sunday was fishing. Over the land could be seen the tillers of the soil—with their long fishing-rods across their shoulders)—making for some quiet pool by which to spend their leisure hours, the still silence being only broken by the distant tinkling of the Sabbath bell calling the more devout to church, but causing no expression of regret to flit across the pleasure-seekers' face.

One could not but be amused by the style of the direction posts on the roadsides; they do not give the distance in miles as we do, but the instructions are conveyed in time, thus:—Staig, half hour; Velp, two hours; and so on. I believe that an hour represents three miles. The carts, drawn by dogs, are also a special feature of the country, all sorts and conditions of dogs working steadily for their daily bread. You find them trotting along harnessed to carts of every kind. It brought to mind vividly Charles Dickens's description of the dogs that kept men; for the dogs here seem, pretty well, to keep a lot of fellows.

My girl friends had got a little cart made for their pug dog, just to give him some idea of what the poor working dog had to endure, I suppose. I photographed him all harnessed ready to trot away; he did not look well pleased. As I was exposing, I remembered the story of the man who was taken up for stealing the carrier's cart, who, when on his defence, swore that that cart had been in their family ever since it had been a small wheelbarrow; and I thought pug's was a very small wheelbarrow, that would never grow to be a useful cart.

The windmill is one of the special features of the Holland landscape. They come into view in all sorts of places likely and unlikely, and the land is so flat that they can be seen at great distances reflected against the sky.

I could not be satisfied without a photograph of a windmill, but found that the nearest available one to where I stayed was six miles away; no matter, I must have it. So my friends, Nellie and Nina, procured for me a neat little cart, and a fat little pony (thick little pony they called it), and thus equipped we crossed the Ysel ferry and, like Don Quixote, rode on to have a tilt at the mill. But I did better than the Don. History conveys the impression that he got awfully riled, whilst I returned home with pleasing impressions.

MARK OUTE.

Our Editorial Table.

PHOTOGRAPHY OF BACTERIA.

By EDGAR M. CROOKSHANK, M.B., &c.
London: H. K. Lewis, Gower-street.

WITHOUT desiring to produce a series of feats in photo-micrography, the author expresses his aim as an anxiety to encourage the attempt to make photography subservient to bacteriology.

After an introductory chapter, in which credit is duly given to some of those who have made investigations in photo-micrography, the author describes the apparatus employed in his own researches. He advises the beginner to commence with a low power and such an object as the blowfly's tongue, then passing onwards until he reaches tubercle bacilli with a one-twenty-fifth oil immersion objective and the limelight.

While he has tried pyrogallie development himself with great success, yet does the author speak in high terms of the iron developer, which he says "has the advantage of simplicity and cleanliness." After a complete treatise on photographic manipulation as applied to photo-micrography, a large number (eighty-six) of illustrations beautifully printed in autotype are given.

This work will necessarily encourage many to apply photography to all their microscopical work, as well as to that department to which it is specially directed. It is well got up.

MARION'S BROMIDE PAPER.

MESSRS. MARION & Co., of Soho-square, have sent specimens of bromised paper intended for being printed by ordinary gaslight under a negative. When making trial of it, we did not at first realise how exceedingly sensitive it was, hence we gave it an exceedingly generous exposure. But as five seconds proved too long, we eventually reduced the time of exposure to one second, the source of light being a gas-flame of average power, and with this we got excellent prints every time.

The developer employed was not strictly that which had been recommended but was some which we had mixed for another purpose, but it answered so well that we have no desire to use any other. It consists of one part of a saturated solution of ferric sulphate to five of potassic oxalate to which six drops per ounce of a twenty-grain solution of citric acid had been added. This gave pure whites and vigorous blacks of a good colour.

The ability to print by gaslight adds greatly to one's enjoyment of photography.

ANTI-COERCION GROUPS.

By A. L. HENDERSON.

It is generally known that the afternoon of Easter Monday was devoted to a series of political meetings in Hyde Park. Mr. A. L. Henderson took advantage of these gatherings to erect his camera on an exceedingly tall stand and take groups of those more prominently engaged in these anti-"coercion" demonstrations. The result is a series of skilfully executed cabinet groups, in which the figures are necessarily small but very distinct.

IMPROVEMENTS IN APPARATUS FOR HOLDING AND EXHIBITING VIEWS AND THE LIKE IN MAGIC LANTERNS.

No. 6431. JOHN THOMAS KEY, Machon Bank, Sheffield.—*May 13, 1886.*

My invention has reference to an improved method of holding photographic views and the like, mounted as magic lantern slides, and for automatically placing the said views or like objects in the correct position before the lens with regularity and precision.

In carrying out my invention, I mount any desired number of photographs, painted subjects or similar "slides" in a circle, preferably by cutting out a series of suitably shaped apertures in a disc of cardboard, papier maché, or other material, and either permanently fixing the subjects therein, or making them removable, so that they can be changed when necessary.

The disc is provided with a centre hole, so that it can be secured upon the end of a spindle projecting from a case containing suitable mechanism, which, when wound up, will cause the said projecting spindle to revolve and carry with it the disc.

The mechanism or clockwork may be of any construction so that it is suitable for the purpose named, and it must be so contrived that its speed of travel may be varied at pleasure, and be instantly stopped and started whenever desired.

The case containing the mechanism may be permanently attached to the lantern or to separate therefrom, and its position may also be varied.

For example, the said case may be fixed in a position above the lens slide in front of the chimney, and so that when the disc is fixed upon the end of the projecting spindle the lowest subject shall be exactly in position with the lens of the lantern. On starting the mechanism, the disc revolves, and the various subjects or slides are successively brought before the lens; if desired, the motion may be intermittent like the seconds finger of a clock, having a rapid movement while changing the subject, and then resting or stationary for a time, or it may be slow and continuous.

The claims are:—1. The combination with a "magic lantern" of a circular mounting frame for holding any kind of views, paintings, or other objects suitable for "lantern slides," and caused to revolve by an arrangement of mechanism, either continuously or intermittently, and substantially as hereinbefore described and as illustrated. 2. For the purpose of showing photographic copies, paintings, or other subjects by the aid of a suitable lantern; a revolving frame or disc having the said subjects mounted thereon, and caused to revolve when desired by means of suitable mechanism, substantially as hereinbefore described and as illustrated.

IMPROVEMENTS IN FRAMES FOR HOLDING PHOTOGRAPHIC AND OTHER PICTURES.

No. 6590. RICHARD MANDER, Branton-street, Birmingham.—May 17, 1886. My invention relates to frames or holders for photographic or other pictures, and particularly of the kind known as screen frames, in which two or more enclosing frames are connected together, so as to hold a series of pictures both back and front, or front alone, and which said combination of frames are arranged to fold up or turn one upon another, screen or book-like; and the principle object of my invention is the jointing and general construction of such frames as hereinafter described.

In carrying out my invention I proceed as follows, and I will describe my invention in connection with a double screen, or a photographic screen in which two frames are jointed to a common middle support or pillar.

The middle pillar support consists of a piece of tubing of the exact height of the frame to be made, with its ends screwed or provided with screwed plugs, which extend a little beyond the ends; and upon the opposite sides of the said pillar hollow beadings or knuckles extend to within a short distance of the ends, and within these hollow beadings the joint pin or wire upon which the frames turn is secured.

The ends or outsides of each frame are constructed exactly the same as the middle pillar or support, with the exception that the knuckle beading is only upon the inside edge, instead of upon the two edges as described.

The tops and bottoms of the frame are made of troughed drawn metal of a V section, with a hollow beading or rib upon its outside edge, and these top and bottom parts I call the carrier ends, from the fact that they embrace and secure the photographs and glasses within the sides of the frame. These carrier tops and bottoms have return ends of the same cross section as the other part; these return ends are of a length equal to the distance between the ends of the pillar and sides, and the ends of the beadings carried by them, so that when the carrier or bracing ends are placed in position, the holes in the beadings of the return parts pass over or on to the joint pins or wires extending from the ends of the pillar and side beadings; that is, the beadings of the pillar and sides become coincident with the beadings of the return ends of the tops and bottoms before named; so that the hollow beadings of both parts constitute the knuckles or joint centres upon which the two flaps or frames turn. The carrier or bracing ends are bound and kept to the other parts constituting the frames by screw caps or screw terminals, taking upon the ends of the tubes forming the middle pillar and sides. The bases of the said caps or terminals are made broad, so as to slightly overlap the tops of the frames.

Instead of having simple beadings upon the sides of the tubes forming the middle and ends of the frame, enclosing sides of the cross section of the top may be employed instead. In this case the inside edges of the frame are made continuous or uniform in character.

The middle pillar with its two side beadings, the sides with the single hollow beading, and the bracing ends or tops and bottoms, with their hollow beadings, are respectively made in one piece, by the process of drawing through or by rolling, or the knuckles may be attached, if necessary, separately, by soldering or otherwise.

By constructing photographic screens as described, the frames are made up of segments or parts, which, when put together, are hinged upon a middle stile or support.

Instead of a twofold screen, a three, four, or any other desired number, may be made in the same way, by providing the inside uprights with double beadings or knuckles to form the joints upon which the adjacent frames turn upon as joint centres, for folding up or opening out.

To introduce a photographic or other picture remove the terminal caps from either the tops or bottoms of the uprights, then remove or draw the enclosing top or bottom from off the pins or wires forming the centres upon which the sides turn; when this has been done slide the picture or photograph between the uprights, with its forward end resting within the trough of the embracing end not removed, then place the other end in position and secure it down by the terminal caps.

Although I have described my invention in connection with a double frame or screen, yet my said invention is equally applicable to the making up of single frames.

AN IMPROVED APPARATUS TO BE USED IN CONNECTION WITH A MAGIC LANTERN FOR ADVERTISING AND OTHER PURPOSES.

No. 6642. MARY WALLACE UTTINO, Woodlands, Anfield, Liverpool.—May 18, 1886.

An apparatus to be attached to a magic lantern for the purpose of moving by means of springs and clockwork machinery a circular disc, and to be placed in

such a position that one of the segments of the disc may be in the focus of the lantern. This disc to be divided into segments, each segment to contain an object intended to be shown by the lantern. The movement of the disc to be regulated by the clockwork machinery so as to bring each object into the focus of the lantern at regular intervals. The apparatus to be of such power that it may be capable of sustaining action for a number of hours. The uses of the above are intended specially for the purposes of advertisement.

The claim is:—The application of any mechanical power or combination for the purpose of automatically changing the objects to be shown by a magic lantern.

IMPROVEMENTS IN PHOTOGRAPHIC SHUTTERS.

No. 7156. ARTHUR SAMUEL NEWMAN, 87, Evershot-road, Finsbury Park, Middlesex.—May 27, 1886.

My invention relates to improvements in the means and apparatus employed for opening and closing photographic shutters, and in regulating the time of exposure of the photographic plate or surface on which the image is cast.

According to my improvements, the time of exposure can be varied from the fraction of a second to a few seconds, or for any time, according to the will of the operator.

For this purpose in carrying out my invention the shutter (which may be of the ordinary kind used for rapid work) is connected to a loosely fitting piston moving up and down in a metal cylinder, into which the air enters, and the time of exposure is governed by the rate at which the air is forced out and re-enters the cylinder. This is effected by means of a series of perforations of graduated size in the top of the cylinder, over which a cover revolves so as to cover or to expose the whole or only a part of such perforations. The larger the extent of the perforations exposed the more rapid is the action of the shutter and the shorter the exposure.

A slot or aperture of graduated size may be cut in the top of the cylinder in place of a series of holes.

The actuating mechanism consists of a convolute wire spring or watch spring which is wound up by an axis or stud on the frame of the shutter, one end of the spring being attached to the rotating stud and the other to the fixed plate or frame. A bar is fixed on the end of the rotating stud, one end of the bar being connected by a link or rod to the piston, and by which it is moved up and down in the cylinder when the stud is turned. When the stud is turned half a revolution, a projection on the end of the arm engages with a catch on the letting-off lever, and retains the shutter wide open for focussing, another half revolution acting to close the shutter again, the spring at the same time being wound up and retained by a projection on the other end of the bar, engaging with the same lever catch as before.

When it is desired to give an open exposure, all or nearly all of the apertures are closed; the shutter is raised, and retained by the catch until released at the will of the operator.

It will thus be seen that the time of exposure can be regulated to any period required, and repeated any number of times or at any interval, and can be set again after other periods of exposure have been used, the resulting speed being always the same, with the same setting.

The shutter may be arranged to act in the diaphragm slot without alteration to lens in any way.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
May 2	Notts	Institute, Shakespeare-street.
" 2	Blackburn

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE technical meeting of this Society held on Tuesday evening was presided over by Mr. W. England.

Mr. H. Trueman Wood exhibited a portable electric lamp of three-candle power. It was originally intended as a railway reading lamp, but had since had a red glass fitted in front so as to adapt it for the dark room. It was made by Mr. Pitkin, and operated by a small storage battery fitted with an adjustable resistance. When charged it would run for seven or eight hours without diminution of light. The principle feature of the battery was that perforated plates of vulcanite were used to separate the battery plates.

The Chairman exhibited a box with levelling screws which he had fitted to the top of his tricycle. In it was contained a quarter-plate camera which could be operated on in the streets without attracting attention. A number of negatives taken by its agency were exhibited. These consisted of instantaneous street views.

Mr. THOMAS SAMUELS exhibited a detective camera which assumed the form of a brown-paper parcel. He promised a description of it at the next meeting.

Mr. JOHN JACKSON (from the Eastman Company) then gave a demonstration

of the whole process of stripping films. It differed in no essential respect from the description given by us three weeks ago [see page 209]. In one minor point, however, there was a difference, and one which conduced to the better working of the process. It will be remembered that we described the preparation of the glass on which the collodion was spread as having been effected by the rubbing over of the surface with powdered French chalk. But Mr. Jackson finds that the end desiderated is better attained by giving the glass a coating of a substratum composed of indiarubber dissolved in benzole in the proportion of one grain to the ounce.

Mr. Jackson's demonstration was highly successful.

In reply to a question as to the length of time that might be allowed to elapse between the developing of a negative on the paper and stripping the film, Mr. W. H. Hyslop said that, as recorded by him in the two weekly journals a few weeks ago, an interval of twelve months at least was permissible.

Mr. Wood spoke of the facility with which he had managed the stripping of films at the first attempt.

Mr. WILLIAM COBB having made an inquiry as to whether Mr. Jackson ever experienced any difficulty in printing by the cockling of the film negatives, elicited from that gentleman a remark that he had not.

Mr. SPIERS had recently taken four dozen negatives which he had stripped. Speaking of certain white marks which he had sometimes seen, he was told by the Chairman that in all probability it was oxalate of lime, which would disappear on applying an acidulated wash.

The possibility of the paper support expanding while wet, and thus distorting the picture, was raised by Mr. W. E. DEBENHAM, but nothing new was elicited on this topic.

A plate holder, the invention of Miss White, was exhibited by Mr. T. Bolas. The next technical meeting will be held on the 24th proximo.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday night, April 21, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. Herbert Starnes presided.

Mr. E. CLIFTON had well washed a print but not toned it; then he kept it a long time until it was yellow all over; he next toned half of it in a borax bath, and it came out all right; he exhibited the two halves to show how the yellow in the whites had toned out in one of them.

Mr. A. L. HENDERSON remarked that the best half of the print would have been better had it been upon freshly prepared paper and toned without delay.

Mr. CLIFTON said that he did not deny that.

Mr. HENDERSON stated that the acetate toning bath had an advantage over all the others in that it tended to give a less mealy print. He exhibited a print of a horse-race in which the running horses came out quite sharp, and all the motionless parts of the scene were blurred; the picture had not been taken by him self.

Mr. W. H. PRESTWICH said that the camera must have moved during exposure in relative proportion to the motion of the horses.

Mr. HENDERSON remarked that that was also his explanation.

Mr. W. M. ASHMAN said that the effect had once been ascribed to movement of the swing back.

Mr. HENDERSON replied that examination of the print did not bear out that view.

Mr. F. W. COX exhibited platinum prints taken upon paper five months old, also some other platinum prints developed with a twenty-per-cent. cold solution of washing soda; the time of development was about ten seconds. The prints were good ones, but not, he thought, superior to those developed in the usual way.

The CHAIRMAN said that the time of development should give a power of checking density.

Mr. J. B. B. WELLINGTON stated that Hubl's book mentions the use of carbonate of soda, says that it has inferior developing powers, and that it throws down a precipitate upon the paper.

The CHAIRMAN remarked that there was no precipitate upon Mr. Cox's prints.

Mr. COX added that the pictures before them had been printed in the first instance very much deeper than usual.

Mr. Wellington exhibited some platinotype prints.

Mr. T. Kerr exhibited some sepia-coloured also some black prints in platinum.

Mr. Wellington exhibited orthochromatic results upon a gelatino-bromide plate dipped in cyanine.

The CHAIRMAN exhibited some lantern slides mounted by means of lengths of the paper slips used in the Morse telegraph printing instruments; he remarked that such strips could be obtained of enormous length, evenly cut. He also exhibited an old-fashioned carpenter's plane for cutting wooden grooving, and some good results which had been obtained by its use.

Mr. A. HADDON asked if any one had tried ammonia for fixing albumenised prints.

The CHAIRMAN thought that Hardwich had, in 1853, proposed its use.

Mr. J. B. SPURGE, in reply to a question, said that the difficulty in the way of introducing his sensitometer to the public on a large scale was the necessity for the previous construction of a set of Whitworth true gauges for boring the holes; to make them singly without such gauges would be too expensive for the purchaser. The sensitometer once made needed no special care; it was always in good order, and it had such a range that sometimes when the smallest aperture just gave an indication there was a reversal of the image on the largest, giving clear glass.

Mr. WELLINGTON had recently seen Professor Dewar excite a luminous tablet at the Royal Institution and extinguish its light by dipping it in cold water; then by breathing on it he brought out the phosphorescence again.

Mr. SPURGE said that with pure bromide of silver he had found the ratio of action equal between daylight and gaslight.

Messrs. A. Watkins and Harry J. White were elected members of the Association.

Next Thursday Mr. Spurge will read a paper upon *Variations of Developing Action as Tested by Spurge's Sensitometer*.

CAMERA CLUB.

ON Thursday, April 21, an address was delivered by Mr. T. Bolas on *Photographic Processes for Book Illustration*, and a most interesting lecture was made doubly useful by the exhibition of a series of blocks and prints in illustration of the subject.

Mr. LYONEL CLARK occupied the chair, and, previous to calling upon the lecturer, drew attention to a simple instrument for timing exposures.

Mr. Bolas then entered upon a description of the processes suitable for printing with type, and treated of methods in regard to lithographic and zinc work, solid photographs, and the means of obtaining granularity. Pretsch's work of twenty-seven years ago he considered had hardly been surpassed. Dallastint was called a secret method, and would, considering its merits, probably have been much more widely used could it have been fully pushed. Blocks and prints of Woodburytype, Dallastint, Messrs. Bullock Brothers' work, Ives's process, and collotype, were handed round.

Mr. GEDDES, in a most interesting speech, pointed out how amateurs might make blocks from their own negatives, and referred to the great pleasure sure to attend such work. He gave a descriptive account of the collotype process and exhibited prints from blocks prepared from Eastman's stripping films, which he strongly recommended as being usable from both sides.

Mr. Bolas remarked that it was a necessary thing to be careful to obtain reversed negatives, and he drew attention to an illustration in an American journal as a fearful example, where the subject was a figure writing with the left hand, and the picture was furthermore defective for several other reasons. It was named *Welcoming an Intruder*, and showed what the Americans could put up with.

Mr. TRAILL TAYLOR did not know what they could put up with in America, but he would like to show some specimens of collotype work done there which he would venture to say were equal, if not superior, to anything done in this country. He had seen it done, and the working was of the simplest description. A smooth and not ground-glass surface was employed. [The prints exhibited were of very fine finish, and, having a burnished surface, could hardly be distinguished from direct photographs.] Mr. Taylor then described a printing process suitable for amateurs, a copper cast being finally obtained.

Mr. W. E. DEBENHAM said that when in Munich, Albert was using only plain glass.

The CHAIRMAN said that the addresses of Messrs. Bolas and Geddes had opened up quite a new field for amateur photographers, and doubtless many present never considered it possible for amateurs to produce printing blocks without going in for a most expensive outfit. He should like to have heard of one or two other processes, examples of which he had come across in the journals, such as that of Fox Talbot and a French (Joubert's) method, a carbon process.

Mr. Bolas described Talbot's process, in which a copperplate is etched by perchloride of iron through a film of bichromated gelatine. The French method (Joubert's) was a collotype process. Gonpil's was similar to Woodbury's, and a roughened gelatine was used.

After some remarks from Mr. GREATHED the proceedings terminated with a vote of thanks to the lecturer and Mr. Geddes.

The next Club excursions will be to Gomshall, Wooton, and Abinger, on May 14, and to Westerham on June 4, both Saturdays.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

AT the meeting held on Tuesday, April 19, at Myddelton Hall, Islington, N., Mr. L. Medland in the chair, Messrs. J. Bird, A. Liddle, and A. Wybrant, were elected members of the Society.

A large number of views taken by members at the Easter Monday outing at Maidenhead was exhibited.

Mr. F. W. COX showed some platinotype prints for the development of which he had used a cold solution of common washing soda instead of the oxalate of potass usually employed.

Mr. George Smith exhibited a quarter-plate camera with a series of lenses of varying focus especially suitable for making lantern-slide negatives.

A large number of slides was then exhibited by means of the optical lantern.

The CHAIRMAN announced that at the next meeting of the Society, on May 3, Mr. Alexander Mackie would lecture on *The ABC of Photographic Emulsions*. Visitors are invited to attend.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the above Society was held on the 19th instant,—The President, the Rev. H. J. Palmer, in the chair.

The following gentlemen were elected members:—Messrs. W. Bolton, Beswick; T. Morley Brooke, Withington; C. F. Budenberg, Whalley Range; J. M. Frankish, Arlwick; A. Hamilton, M.D., Ashton-under-Lyne; Walter Noar, Lower Broughton; and James Shaw, Great Ancoats-street, Manchester.

Mr. J. G. JONES read a paper on *Gas Bags versus Gas Bottles*, describing the advantages, and comparing the first cost and also the cost per hour of each system of lantern illumination.

After the discussion by the members of queries taken from the question box, Mr. J. E. THORNTON exhibited his patent roller slide, and also exhibited a small detective camera.

Mr. LACHLAN M. LACHLAN, by request, exhibited a negative and prints of his large photographic group, *The Royal Family at Windsor*, and gave some details of the work in taking the same. The members were given an oppor-

tunity for inspecting the large negative, which was a remarkably fine one, and capable of yielding prints four feet four inches by two feet two inches.

Mr. E. Briggs showed a series of lantern slides, using the lantern recently presented to the Society.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE ordinary meeting was held in the College of Science, Newcastle-on Tyne, on the 12th instant,—Professor Herschel in the chair, when

Mr. JOHN JACKSON, of the Eastman Dry Plate and Film Company, gave a demonstration of the Company's new stripping films. All the various operations were successfully carried through and followed with close interest by a numerous attendance of members and friends. The specimen negatives and prints were much admired.

The usual vote of thanks was proposed by the CHAIRMAN.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

A MEETING of the Society was held April 6, 1887,—The President, Mr. Frederic Graff, in the chair.

A question in the box asked, "Is there any method of toning positives on glass?"

It was stated in reply that lantern slides were frequently toned in solutions of sulphuret of potassium, bichloride of palladium, and bichloride of platinum.

Mr. WALMSLEY suggested slightly under printing the slides, bleaching with bichloride of mercury, and then toning with sulphite of soda. As the latter acts as an intensifier, it is necessary to print light, or the slide will be too dense.

Mr. BARTLETT directed attention to an intensifier for gelatine plates which he had received from Mr. John G. Cassebaum. It possessed marked advantages over mercury, being gradual in its action, perfectly under control, and affording any degree of intensity required, without interfering with the printing qualities of the negative. It is necessary to submit the negative to be strengthened to a preliminary bath to make it slightly acid. This bath consists of—

Nitric acid	10 drops.
Chromic alum	1 ounce.
Water	20 ounces.

Citric or acetic acid may be substituted for the nitric in the proportion of one ounce to twenty of water.

Stock solutions are made as follows:—

A.	
Gallie acid	120 grains.
Alcohol	1 ounce.
B.	
Silver nitrate	30 grains.
Water	1 ounce.

One drachm of each of the above solutions is added to each ounce of water. The plate is put in an ordinary developing dish and the solution poured over and gently rocked to and fro. The negative will gradually come up and may be carried to any degree of intensity. Mr. Bartlett also mentioned the investigations of Dr. Lobse on the modifications of the alkaline developers for bromide of silver plates, as published in the *Photographische Correspondenz*. Dr. Lobse, in his trial of the various alkaline earths in connection with pyrogallie acid, found that borax (bi-borate of soda), contrary to his expectations, proved perfectly inert, producing not the slightest action upon the latent image. He further found that even the addition of soda or ammonia produced no action, while the borax remained present the plate lay perfectly white in the dish. It was only after washing out the borax from the film that the action began and was completed. The borax does not neutralise the action of the light, but prevents the reducing action of alkaline pyro developer. He accordingly suggests that this salt might be of advantage as a retarder in the developer. Mr. Bartlett, acting upon the suggestion, added one drop of saturated solution of borax to the ounce of developer, and found that the addition acted as a clearer of the negative without any appreciable retardation of the development.

Mr. JOHN G. BULLOCK showed a chart which had been brought to the meeting by a visitor, which was a valuable aid to those who were called upon to photograph buildings or other subjects requiring to be taken from some special point, to obtain the best effect with a certain sized plate or with any special lens. A base line was ruled across the bottom of the chart and a perpendicular line down the centre. From the point of intersection the angles radiated, and were ruled off on either side of the perpendicular line, every five degrees being shown, red and black alternately, making it easier to trail them up. Perpendicular lines were ruled on either side of the centre at distances corresponding to length of all plates used. The central vertical line was graduated in inches and centimetres. Horizontal lines were laid off of a length corresponding to the longest plate each lens would cover, and at a distance from the base line corresponding to the equivalent focus of the lens. The angle line, intersecting lens line, and plate line, would give the angle included and the particular size of plate, and any number of lens foci could be laid down, and the angle of any lens or size of plate could be seen at a glance. The chart shown was 22×26, but angles of lenses of longer focus could be read by taking half the focus and half the length of plate. Mr. Bullock also mentioned a peculiar circumstance in connection with a copying lens recently imported by Mr. Partridge, a member of the Society. It was found that from some cause, at first unaccountable, every plate exposed with the lens was slightly fogged. New baths and developers of all kinds were tried, and camera and dark room were carefully examined for cracks where light might leak in. A critical examination of the lens revealed the fact that owing to the angle at which the inner end of the lens's mount was bevelled its extreme inner edge was struck by some of the rays of light after passing through the lens, and they

were reflected in the shape of diffused light upon the plate, thus causing the fog. The difficulty was entirely overcome by use of a cardboard diaphragm so placed as to cut off these rays before they reached the reflecting edge of the mount.

Correspondence.

Correspondents should never write on both sides of the paper.

GELATINE PLATES FOR COPYING LINE WORK.

To the Editors.

GENTLEMEN,—Referring to your article in the JOURNAL of the 15th instant on this subject, I venture to make a suggestion, namely, print on Eastman paper instead of silver. A moderately dense negative, such as can easily be obtained on gelatine plates with ordinary development, will give absolutely black and white prints if worked with artificial light such as gas. Moreover, the colour and surface closely approaches the original. I have a pencil drawing so copied that few persons could detect that it was a photograph at all. Of course Eastman paper is dearer than albumenised, but the result for line work is so infinitely better, and the fact of its being capable of being used at night greatly mitigates this disadvantage, to say nothing of the rapidity with which a number can be printed. If there is no changing of negatives, once the exposure is lit off a dozen can be readily done in an hour (washing, of course, excluded). I enclose one or two specimens, which kindly return at your convenience.—I am, yours, &c.,

GREENWOOD PIN.

P.S.—Last autumn I copied a large series of parchment deeds, in many of which much density was difficult to obtain, but on the Eastman paper, in most cases, obtained good results.

G. P.

META-BISULPHITE OF POTASH.

To the Editors.

GENTLEMEN,—Allow me to add my testimony to Mr. Pringle's as to the excellent keeping qualities of pyro solution with meta-bisulphite of potash. I have used, by chance, exactly the solution he suggests, namely, ten per cent. pyro and five per cent. meta-bisulphite, for about a year, and have kept it at least six months without the least apparent change. Instead, however, of a mere ten per cent. bromide solution as a restrainer, I have used for a long time past one containing ten per cent. bromide of potassium and an equal quantity of citric acid, which may be preserved from mould for an indefinite time by the addition of a small lump of camphor. (I may remark that camphor is equally effective in preserving gum mucilage.)

For developing most makes of rapid plates, I find that twenty drops of pyro, five drops of restrainer, and ten drops of twenty-five per cent. ammonia to the ounce, forms a very good standard developer. For under exposure the ammonia may, with many makes of plate, be doubled, while for over exposure I always keep a spare cup at hand, with, say, fifteen drops of restrainer in it, and if the image comes out too soon or the details follow the sky too rapidly, I pour the developer into it, and back on the plate, when development is almost instantly checked, and when started again with five to ten drops more ammonia will give as much density and contrast as is required. If insufficient detail appears, a less restrained developer may again be resorted to.

I do not know what "latitude of exposure" is admissible with this mode of development, but it is certainly much greater than with any reasonable quantity of plain bromide. As an experiment, I once exposed two Paget XXX plates under a negative, one four times as long as the other; the shortest was quite fully exposed, while the longer developed into a plucky transparency so clear in the lights as to be used successfully in the lantern, and this does not at all represent the limit of what may be obtained.—I am, yours, &c.,

HENRY R. PROCTER.

Tynemouth, April 24, 1887.

P.S.—I think that where the drop bottle is used the strength of the pyro solution might be doubled with advantage.

AN AUTOMATIC PRINT WASHING WHEEL.

To the Editors.

GENTLEMEN,—In THE BRITISH JOURNAL OF PHOTOGRAPHY of January 7, 1887, in a leading article on the washing of bromide prints, much stress is laid on the importance of direct washing with water from a rose, as by this means the hypo is more thoroughly eliminated than by much soaking, even in running water.

Actuated by the above, I have had an automatic print washing wheel made by the local tinsman, and I find that it works well. I therefore venture to send you a description of it, as I believe it will prove useful to amateurs, and as I hope that the principle is capable by extension of being utilised on a large scale. The principle is that of the overshot water-wheel. Fixed round the circumference of a light wheel is a series

of tin plates, each turned up at one border into a trough. The prints are fastened on these plates and are washed by water from a rose; this water, by filling the troughs in succession, turns the wheel.

To enter into details, I had better describe a wheel which I have had made for washing twelve cabinet prints at a time. It is two feet in diameter and three inches wide. Round its circumference it carries twelve tin plates with their troughs. The plates overlap the wheel by two inches on each side. Their side edges are turned up a quarter of an inch to keep the water on them. Holes are bored through the plates in positions corresponding to the corners of different sized prints, and the prints are retained in position by means of ordinary pins passed through these holes into pieces of cork at the back.

The rose is a flat one, seven inches wide and tapering to a supply tube three-quarters of an inch in diameter. At its lower end, where it is seven inches wide and one inch thick, it has a single row of small holes three-eighths of an inch apart. This rose allows enough water to wash the prints. It does not waste the water supply, as it uses about nine gallons in one and a half hours, and it suffices to turn the wheel. In fact, it is necessary for the lower segment of the wheel to work in a trough, with a depth of water varying according to circumstances. The water in the trough acts as a break in preventing the too rapid revolution of the wheel, and it further washes the prints.—I am, yours, &c.,

S. L. DORIE, *Surgeon-Major, 4th Madras Cavalry.*

Kamptee, India, March 30, 1887.

P.S.—In practice it will be found that the prints, on thick or thin paper, adhere, when wet, to a smooth surface so firmly that they need no pinning on to the wheel.

THE LATE J. B. OBERNETTER.

To the Editors.

GENTLEMEN,—The following are some details of Obernetter's career which have just come to my hands; they might be interesting to your readers.

J. B. Obernetter was born on May 31, 1840. He studied chemistry at Leipzig in 1858 under Professor Erdmann, and subsequently at Heidelberg under Bunsen, and finally at Munich under Professors H. Pettenkofer, Liebig, and Kaiser, all more or less great authorities. Upon Liebig's recommendation he devoted himself to photography, and entered the atelier of Albert, where he made his first two inventions, enlargements on developing paper and a process of photography on porcelain. Establishing himself in 1863, Obernetter soon produced the well-known collodion-chloride paper a few years later. Upon the suggestion of Albert, his former employer, Obernetter worked out his process of phototype "Lichtdruck," which was afterwards bought by Albert and further perfected by both. Obernetter further simplified and perfected it by his dusting-on process with graphite, for which he obtained the gold medal at the Vienna Universal Exhibition. Upon the suggestion of Dr. Maddox for a gelatine instead of a collodion emulsion (1880), Obernetter worked out and soon produced a gelatine emulsion, which still enjoys an unequalled reputation. His gelatine emulsion paper, produced some time later, has also gained a great reputation already, and is only surpassed as an invention by his yet more important work, the production of an orthochromatic plate for landscape work applicable without the yellow screen.

Last, not least, is to be mentioned his invention of a process of photo-copper printing by direct transfer of the image from the negative to the copperplate—a process for which we may anticipate a great future yet.

He died on the 13th instant from syncope of the heart, after a few days indisposition.

We may well lament the loss of a man who has done so much for our art and from whom, had he lived, much more might yet have been expected.—I am, yours, &c.,

J. R. GÖTZ.

19, Buckingham-street, Strand, April 25, 1887.

COLONIAL AND HOME GRIEVANCES.

To the Editors.

GENTLEMEN,—As our Colonial brethren are airing their woes, will you permit me to give a statement of the treatment some of the home customers of London stock-houses obtain? A month or so back I bought from a firm a 10 × 8 universal studio camera, warranted perfect and complete, to take two *cartes-de-visite* on a half-plate, two cabinets on a whole-plate, single whole-plate and 10 × 8. "Monitor" will please note that this was a make of camera of which large numbers have been sold, and was sold as new and of the most modern and improved pattern to a professional photographer, and without complaint on seller's part of any unreasonableness on the part of the purchaser. Well, I got the makers to cut the fronts for a 2u and a 10 × 8 lens respectively, and when the camera came to hand I set to work and placed the 2u on its front; but on trying the 10 × 8 flange, found the opening in the camera front far too small for the flange—this in a camera specially made for a 10 × 8 portrait lens, i.e., one of 4½ diameter!

On seeing the makers they were very sorry, they knew the front was too small, and had determined not to have any more like it, and if in any

way they could possibly fix the lens on, short of making a new front to the camera, they would be pleased to do it.

After a lot of scheming I made a makeshift, and fitted the lens upon the camera. I then proceeded to take a group of children, and, having focussed, tried to throw up the screen and insert the dark slide, but the handle of the focussing screw stood upright and prevented the screen from moving. I shifted the front of the camera a short distance on the off chance that when the group was again focussed the handle of the focussing screw might be downward; by chance it was so, and the picture taken. The camera was then examined, and two hours wasted while the screen was removed and a gap made in the frame of it sufficiently large to permit it to clear the handle in all positions. On examining the shifting screens at the back, they were found to be made for Malvern, promenade, and boudoir, instead of *cartes-de-visite* and cabinets, as the carriers in dark slide were.

The next thing was, that when two *cartes-de-visite* were taken on a half-plate one picture was always out of focus, and a close examination of carriers showed that the half-plate one had been planed away in the rebate at one end to the thickness of stout paper!

In addition to the stupid weakness of the carriers, they have about half an inch of side play, and any one who knows the large amount of light in the modern dark room will see the advantage of this when squeezing two cabinets upon a whole-plate. When the camera is racked out to take a large head the bellows go flat, being about three folds too short, and when you are taking a smaller size the camera front has such slack side guides that it is possible to get it half an inch out of parallel with the back unless you take a rule and measure it.

But why make a fuss about such a trifle as that? one is not always copying! And if the carriers are only one-eighth thick where strength was needed, you have good half-inch timber in the back screens where a piece of thin zinc would have been sufficient.

I have enclosed a piece of the half-plate carrier for the inspection of the Editors, and shall be pleased to show the camera to any gentleman who will honour me with a call.

J. D. COOPER.

Montague Studio, Kingston, S.W.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—I have watched the correspondence in your columns on the right to the negative, and the many *absurd* reasons put forth by people who ought to know better why the negative can be demanded by the client. No negative is ordered or paid for, but a number of photographs, one or many, as the case may be, which are paid for, and there is an end of the matter. Of course if you bring the intricacies of the law to bear on the subject *there is no end to it*.

I should not hesitate, if in Mr. Debenham's position, to let the party have his negative, and charge him 20s. per year for warehousing and care of negative (or more); that might settle the matter. Certainly no court of law would refuse so modest a demand. Query, Why should photographers be supposed to use negatives at all? Are we obliged to say how we produce our work? I am not a high authority, but I think this is to the point.—I am, yours, &c.,

FREDERICK BARBER.

1, Orchard-street, Church-street, Sheffield, April 23, 1887.

To the Editors.

GENTLEMEN,—There has been a considerable amount of writing on the subject of who is the owner of the negative. I have read it carefully, hoping that some abler pen than mine would point out where, in my opinion, the gist of the matter lies, but none have yet done so. It is this—Is it, or is it not, the practice to charge more for the first supply of prints than for subsequent orders? If so—and I think it is—is not the extra charge for taking the negative? And, if so, how can the photographer claim as his that for which he has been paid?—I am, yours, &c.,

J. E. G.

PHOTOGRAPHING ON DEAL PIER.

To the Editors.

GENTLEMEN,—I can fully confirm your statement about the restrictions at Deal Pier.

Some years ago there was a large fleet of vessels anchored in the Downs off Deal. I was at that time visiting there, and having my camera and tent with me was anxious to obtain photographs of the fleet from the pier head. The toll-keeper, however, refused me access, and I then sought out the Manager of the Company, Mr. Laidlaw, who, notwithstanding my informing him I was only photographing for my recreation and amusement, refused to sanction my going on the pier with my camera, informing me a local photographer had the sole right.

This degrading the right to photograph at any point of interest to a money question is one of the things that tends to give photography such an elevated status that it has occupied lately, and to develop those feelings of cordiality between the amateur and professional which used to exist.

I have often sat and sketched on Deal Pier, but the nice distinction between a sketching block and a camera is apparently now reduced to a question of money payment.—I am, yours, &c.,

FRANK HOWARD.

Wallingford, Berks, April, 1887.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, camera in exchange for portrait lens by Slater.—Address, J. COLLINGS, Photographer, Nelson, Lancashire.

A diffraction grating in exchange for first-class 12×10 or 10×8 lens for architectural purposes.—Address, G. W. VALENTINE, 156, High-street, Southampton.

Will exchange a musical album, playing two tunes, for two double dark slides (Lancaster's quarter-plate instantograph).—Address, GOWER, Vicarage-road, Teddington.

Rock bnmisber, a six-inch roll, and a twelve-inch roll, in exchange for portable camera, not less than 7½×5. Difference adjusted.—Address, G. W., Photographer, Grange-over-Sands.

Required, a whole-plate camera suitable for outdoor work in exchange for a nine-carat double gold chain with tassel appendage.—Address, EDWARD J. HUGHES, Graigue, Co. Kilkenny.

Wanted to exchange, Grimston's whole-plate pneumatic shutter (fits into slot of Ross' rapid symmetrical lens) for Guerry's flap shutter, same size.—Address, F. HOARE, Coxwell-court, Cirencester.

Wanted, good half-plate lens, either Ross' or Dallmeyer's rapid doublets preferred, for Meagher's 5×4 tourist camera with three doubles, &c.—Address, F. W. TREADWAY, 26, Trinder-road, Crouch-hill, N.

I will exchange a 5×4 camera, with two double dark slides and one single slide, for a half-plate camera with three double dark slides. Difference in cash.—Address, W. MARSHALL, 13, Ripon-street, Moor Park, Preston.

Wanted, a 12×10 tourist camera, with two or three double dark slides, in exchange for a whole-plate camera by Dallmeyer, with three double and one single dark slides, and a 8½×6½ rapid doublet lens.—Address, W. BOND, Photographer, Bank-place, Norwich.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

COL. GUBBINS.—All the four gentlemen mentioned are amateur photographers.

ESLAFFORDE.—We have already invited photographers to send us specimens of spotted prints, and the details of the circumstances under which they appear.

J. BROWN (Pontefract).—It is not advisable to use zinc for the purpose unless the metal is well protected with Brunswick black or other impervious varnish.

E. L.—Out of the lenses you name B will be the best for cabinet pictures; A is too short a focus for taking good cabinet portraits. It would have to be approached too close to the sitter.

S. J.—The oval rims and glasses for photographs mounted in optical contact with the glass are supplied by Messrs. Marion & Co., Soho-square, and by most other dealers in photographic requisites.

RETOUCHER.—The only plan we can suggest is that you advertise for negatives such as you require. Perhaps one of your photographic friends may lend you a few, and that would answer your purpose.

ARTHUR MAYCOCK.—With enamelled photographs the spotting must be done before the print is treated with the gelatine, and not after the picture is finished. We know of no preparation for spotting enamelled prints after they are mounted.

T. T. L.—Without seeing the negatives or knowing more of your method of working it is impossible to give the reason why all the skies in your pictures print dark. Possibly the skies were dark when the negatives were taken, or, it may be, that they are much over exposed.

T. A. ELWORTHY.—From the fact that the prints have changed so rapidly it is clear evidence that they were imperfectly fixed. Five minutes immersion in solution of hyposulphite of soda, one ounce to the pint of water, is far too short. You had better go back to your old method of fixing if you desire your pictures to be permanent.

TONING BATH.—The pink colour in the toning bath is due to a reduction of gold from some cause or other—probably by some foreign substance introduced either with the prints or on the fingers. It is possible that the discolouration may be due to the action of light. A toning bath when out of use should not be exposed to a strong light, as that will tend to reduce the gold.

CAPE TOWN.—Your lens is an orthographic of somewhat long focus. You can ascertain the length by approximately focussing the sun, and then measuring from the point to the front surfaces of the anterior lens. If you employ the lens for portraiture you will require a very long camera, and the sitter will have to be placed at a long distance from it. These lenses give exceedingly fine definition, and are very useful instruments.

STUART L. LEONARD writes: "In THE BRITISH JOURNAL OF PHOTOGRAPHY of last week, in the report of the proceedings of the London and Provincial Photographic Association, mention is made of a neat little portrait lens very suitable for a detective camera; could you tell me where such a lens is to be procured, as it is just the thing I want?"—The lens alluded to is one of the Petzval form, and is known as the instantaneous stereoscopic lens. It may be obtained of either Messrs. Ross or Dallmeyer. Some other firms also supply a similar lens.

C. B. VANDOEUR says: "I should feel much obliged if you would inform me, in your 'Answers to Correspondents,' how to get rid of a stain on a negative which was produced while intensifying in the following manner:—After bleaching with a solution of bichloride of mercury I omitted to wash the negative thoroughly, and on pouring on the ammonia solution it became badly stained."—Stains of this description can seldom be removed. Sometimes a solution of cyanide of potassium will help matters. Possibly some of our readers can help our correspondent.

D. BENNIE asks: "Would you kindly answer me on the following through the JOURNAL? I have got two *carte-de-visite* cards handed in to me to try and copy them; they are very old and much faded. Is there any means by which they could be revived a little?"—If the prints be removed from the mounts and immersed in a dilute solution of the bichloride of mercury any yellowness in the prints will be removed, but no detail which has faded out will be restored. Yellow and unpromising looking prints frequently copy very much better than they at first sight might be expected to do. Our correspondent should make a trial with the pictures as they are before resorting to other treatment.

C. P. writes as follows: "Having decided to go in for enlarging by artificial light, I intend to buy a nine-inch condenser (double), and I have an enlarging box. 1. Will you kindly answer me what is the best light that will give an uniform white strong light (not the electric or limelight), and at the same time giving a sharp image?—2. Will an Argand gas burner answer better than either ordinary oil lamp or gas?—3. Would the nine-inch condenser answer well for enlarging from either quarter or half plate, as I am in the habit of enlarging from the half-plates? I have always enlarged by daylight, but I found that the light is always unreliable and changing."—In reply: 1. Any of the best forms of paraffine lamps will answer, so will magnesium. It is a good plan to place a diaphragm with a moderate size opening between the light and the condenser.—2. An Argand gas burner will give a very good light for the purpose, particularly if the diaphragm be employed.—3. A nine-inch condenser is a very suitable size to use for half-plates. As a rule, better results will be obtained with daylight than with artificial, unless the source of light be a point, as in the case with the electric or the limelight. A little judgment will enable the variations in the light to be compensated for.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, May 4, 1887, will be *On Photographing Animals*.

MR. HAROLD BAKER (late H. W. Cox), Birmingham, sends us two excellent cabinet portraits of Mr. W. Jerome Harrison, for which we thank him.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next the subject for discussion will be *The Variations of Developing Action as Tested by Spurge's Sensitometer*.

SPORTSMAN'S EXHIBITION.—At the present time there is open in "Olympia" a Sportsman's Exhibition of a very attractive nature. Here are to be found everything in which photographic amateurs are known to delight, including fishing, shooting, and boating appliances, tricycles and bicycles, together with, of course, photographic instruments. It is under the management of Mr. Harry Etherington, to whose energy the exhibition owes its success.

A SOMEWHAT clever feat was accomplished on Monday evening. At the close of the performance in the St. James's Theatre the actors arranged themselves on the stage, and were photographed by Mr. W. H. Hyslop from the front of the dress circle. The only light employed was that from the sun-burner in the roof supplemented by that from the footlights. The exposure given was the unusually rapid one of six seconds, with a lens having an aperture of $\frac{1}{8}$. The plates were orthochromatic.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION, 181, Aldersgate-street, E.C.—A special general meeting will be held on Thursday, May 5, at half-past seven p.m., to confirm or otherwise amendment of rules made by special committee. Rule 4, last clause to read, "Donors of one guinea and upwards shall be entitled to vote at general and special meetings, also at the election of pensioners, and shall further have the privilege of recommending for the consideration of the committee cases of non-members such as are defined as urgent in rule 13." Rule 10, line 15, after "applicants" insert "or cases recommended by donors under rule 4."—H. HARLAND, Secretary.

No. 1409. VOL. XXXIV.—MAY 6, 1887.

PHOTOGRAPHS OF MACHINERY.

IN our recent observations upon this subject we left for further treatment sundry questions of importance which could not be sufficiently dealt with in the compass of a single article, and we now return to their further consideration. We take it for granted that no one would essay this kind of work without a complete set of lenses of various foci, all of which in turn will be found to be needed, seeing that any object may be embraced, from the smallest to the largest, from a donkey pump to a locomotive, and from that to the *coup d'œil* of a large machine shop, and from standpoints of all degrees of proximity and of distance, of convenience and inconvenience. With regard to the latter, we may say that the operator for one firm we know of, before he sets out with his camera, always dons a special suit of clothes to which he attaches little value—somewhat after the fashion of those provided for visitors to a coal mine.

We have already given the opinion of one contributor in regard to the kind of camera to use, or, rather, to avoid, that is to say the one with a free tailboard; and there is the further advice to give, that the camera be provided with double swing back. It is needed from opposing points of view—to assist in focussing and to avoid perspective representation. When the object is under extremely poor illumination, as will often happen, it will be necessary, even with dry plates, to work with a maximum aperture, and then from the cramped positions and close quarters so often inevitable, it will be found that a well-focussed image cannot be obtained without "stopping down." Here the swing back is of marvellous usefulness; a slight deviation of the side swing will bring up into complete sharpness a most unpromising image. But it must ever be remembered that when the swing is employed for this purpose any perspective representation of lines will always be intensified. There will be cases where this will not matter and where everything must be sacrificed to the mere obtaining of a sharp image of any sort, but where there is sufficient light the swing back should never be used to facilitate focussing. Looking at the use of the swing back from the other point of view, it will be found invaluable when a picture is needed in which no perspective representation of lines is permissible, where something more of the nature of a geometrical "elevation" is required. Those not accustomed to this refinement of machine requirements may be reminded that whether the front face of the machine be presented at an angle to the axis of the lens in a vertical or horizontal azimuth, all that is needed is to make the ground-glass of the camera parallel to that face. The parallel lines of the machine then will be truly depicted as such on the plate. As this condition is just the

opposite of that needed to bring the retiring portions of the object into focus, it is evident that a small diaphragm will be absolutely essential if all parts of the machine are to be crisply depicted.

It is now no longer a secret, as it once was, how the beautifully smooth and even appearance of the surface of the machine given in some of the early photographs of this class was brought about. If this is considered essential—and that it is, or should be, is clearly shown by two photographs with smooth and with rough surfaces now before us—the machine has to be specially prepared. It must be photographed before the final coat of paint is given to it, and be specially prepared by painting in slate colour, in "flattening," as it is termed—that is to say, the paint almost entirely diluted with turpentine, little more oil beyond that contained in the paste colour being used. Quoting again from the photographer before named, whose experience in this kind of work we know to be most extensive, he informs us that the workmen who are put to this painting need constant looking after lest they put too much oil in their paint pots, the consequence being that bright patches appear here and there, and quite spoil the effect, there being no comparison between two photographs, one from a machine with a well flattened, and the other from an imperfectly dull, surface.

In developing the negative the photographer's efforts must always be devoted to obtaining negatives as free from fog as is possible, that great enemy to clearness of shadows, a smoky atmosphere, being naturally very prevalent in shops where large numbers of workmen are constantly engaged, and where furnaces and furnace chimneys too often load the atmosphere with fine particles that are fatal to transparent shadows. In such instances it will be useless to attempt working if the sun's beams pass between camera and object, and another time of day must be chosen when this effect does not obtain. Even when this contingency can be avoided it will be found always desirable in development to use a minimum of ammonia and an unusual proportion of bromide. In fact in many cases it will be best to arrest the development at an early stage, and, instead of pushing it to full intensity of image, to obtain the needful depth by after intensification by means of mercury followed by ammonia. If hydrosulphuret of ammonia solution be employed there need be no fear of the negative fading when proper washing has been given between the various operations. We have seen large numbers of negatives so intensified years ago which have never given way, though when ordinary ammonia solution is employed there appears less certainty of permanence.

It will be found that many manufacturers require white backgrounds, and these of course can only be obtained by

painting out, which sometimes is a most laborious operation from the intricacies of the outlines presented by some machines. It will be well in such cases for the photographer to have two prices, one for machines with the workshop background, and the other for those with white ground. Paper—i.e. an untinted silver print—should be adopted as much as possible for stopping out, to avoid labour and loss of time, and where paint is needed for the finer details, Indian ink must be eschewed—it is too apt to split and raise the varnish. Some photographers use ordinary black varnish for the purpose, while others employ water colour (not moist colours) containing as small a quantity of gum as possible. One gentleman, who makes a speciality of machine photography, informs us that he always employs "Gihon's opaque."

We believe that we have now touched upon all the points of importance in connection with this useful kind of photography that would not at first occur to those unaccustomed to it, and we trust that our hints may be found useful to those who have any thoughts of attempting a branch of photography which is both lucrative and likely to be in increasing demand.

WE are pleased to learn, both from private sources and also from a letter in another page from the genial ex-President of the Society of New York Amateurs, Mr. F. C. Beach, that Mr. W. K. Burton, while *en route* for Japan, has been well received by the amateur section of the New York photographers. It was, of course, only politeness to the nationality of his entertainers that prompted Mr. Burton to institute a comparison between the alleged readiness displayed by the American photographer in imparting information freely to the public, and the dark contrast afforded by the alleged reluctance of the English photographer in divulging information, such comparison being seemingly to the disadvantage of the latter. The fact is that Americans have never been slow in stating how much they were indebted to the British for information openly given.

THE example set by Mr. W. H. Hyslop (with whom, by the way, we omitted to associate Mr. Lyonel Clark) of photographing the actors on the stage of the theatre by the ordinary lights employed, has been followed in a most successful manner by another member of the Camera Club. Mr. John F. Roberts has very skilfully laid siege to the Criterion Theatre, and has captured *David Garrick*, or, more correctly, the actors while taking their part in that drama. Everything is as well done as if the photography had been done by daylight in a studio. We shall next be having the courts of law, and (who knows!) even the church itself, and their inmates, falling victims to the all-conquering photography.

It is tolerably well known that faded paper photographs may be "restored" by treating them with a solution of the bichloride of mercury. Although the prints are said to be restored, the term is really a misnomer, for no detail which has actually disappeared is recovered by the treatment; it is only the yellowness of the print which is removed, and this causes it to look bright and fresh, and, in a measure, restored. At the same time that the yellowness of the image is destroyed its former tone is changed, and rendered much warmer than it was originally. It will be interesting to learn whether pictures, after they have been renovated by the bichloride of mercury, undergo a further change, or if they can be considered permanent. This, of course, is a difficult question to answer, but we may mention that we have in our possession a number of prints which were experimented upon twenty-two years ago, and not one of them appears to have changed since. The mercurial method of renovating faded photographs was introduced about thirty years back, and it would be, as we have just intimated, desirable to know how far prints, after the bichloride treatment, will resist the action of time, and whether they may be designated "permanent." If some of the earliest examples of this system of renovating were forthcoming, they would prove instructive.

At the Astronomical Congress in Paris it has been decided to map the entire heavens by means of photography, and gelatine plates will be used for the purpose. We have seen many commercial dry plates which would yield a good display of the celestial bodies, in the shape of stars, comets, and the like, without being exposed to the sky at all. The question has often been put by the uninitiated as to how the tiny images impressed by the stars are to be distinguished from accidental spots in the bromide film. In most cases this would indeed be difficult if only one negative were taken; but the observations are never confined to a single plate, as several are always exposed. Then, by comparison, the images of the stars are easily distinguished from accidental blemishes in the film.

NOTWITHSTANDING that we have before directed attention to the fact, many photographers, who are constantly sending negatives through the post, do not appear to be aware that the Post Office now take a certain degree of responsibility in case of loss or injury to goods forwarded by Parcels Post. The liability is limited in amount to twenty shillings. But any parcel can be further insured up to the value of ten pounds for a very trifling sum. For a fee of a penny compensation to the amount of five pounds will be ensured, and for twopence to the extent of ten pounds.

To secure compensation for damage from the Post Office, the parcel must be distinctly marked with the words, "Fragile—With Care." Parcels or letters so labelled, it may be as well to mention, may be somewhat longer in transit, because the Office reserves to itself the right to select the route by which they shall travel. Such parcels, we understand, are not received by, or delivered from, trains while they are in motion, as is the case with the ordinary mail bags. Many negatives transmitted through the post are worth to their owners more than the maximum sum mentioned, but it may be somewhat doubtful if the authorities would willingly pay this amount, in the case of the breakage of a negative, unless ample proof were forthcoming of its absolute worth. In a case tried some years ago where a railway company were sued for compensation for a number of valuable negatives that were broken, their value was assessed by the Court at the cost of the glass, and a trifle in addition for the chemicals upon it.

THE *Echo*, a few evenings since, while commenting on the fact that the attitude assumed by artists towards photography has materially changed during the past twenty years, says, "The portrait painter, it is whispered, makes constant use of it to catch fleeting expressions on the sitter's face, and the landscape artist carries a camera with him on his sketching expeditions into the country." Has this not always been, more or less, the practice from the very earliest days of photography? Possibly, at that period, the painters did not, as many do now, do their own photography, but they nevertheless had it done for them. We can point to pictures executed thirty years or more ago—and which are now in our National collection—that were, to a large extent, painted from photographs. At one time a painter would consider it *infra dig* to openly recognise photography at all. But now the case is altered, and the majority of the leading artists frankly admit that photography is very valuable. A few, it is true, qualify the admission by adding for "some purposes."

ANENT the subject of backgrounds by the powder process as described last week. It may be mentioned that this method is particularly well adapted for the production of landscape or other artistic backgrounds. When these are required, some of the stock colour (see previous article) should be taken and different proportions of black or white mixed with it as occasion may require. Then the colour is moistened with water and moulded into lumps or sticks, and dried. In the dry state the sticks are used as chalks or crayons to draw or sketch on the background the design required. The sharp lines made by the crayons are afterwards softened off, by rubbing them over with the brush, or, in some cases, with a pledget of loose felt or flannel, followed by the brush. The sketch may be made on the background, either while it is wet or after it has become dry. In the latter case, however, the canvas must be wetted afterwards in order to fix the colour and prevent its eventually rubbing off. The wetting, in this instance, must be done from the back of the canvas and not from the front.

THE RIVAL PHOTOGRAPHERS.

To all who have very pronounced ideas as to what constitutes the art of photography, the following may not be altogether uninteresting. It is only by the interchange of ideas and the ventilating of experiences that a sound judgment can be formed as to the merits or demerits of any branch of art or other subject that may be open to discussion. The one, in connection of course with portraiture, that these few lines may seem to favour, has always been, but more especially of late, a kind of *bête noire* alike to the photographer and the independent artist. Notwithstanding, however, the object of their mutual revilings, if not absolute contempt, lives—I cannot say, flourishes. More than half the arguments used against him are created and carefully reared up by the revilers themselves. They have only themselves to blame, too, for the shortcomings which would never have existed had it not been for the weakness—I will not say cupidity—of those who should naturally order the situation.

In an important and wealthy town, not quite ten thousand miles from every place, there were two more or less prominent photographers. One was a man not only skilled as a manipulator in photography, but also endowed with a very great amount of artistic genius; indeed, he had been in repute as an artist (may I say *properly so called*?) long before he ever invested in a camera and lens, and dived deeply into the mysteries of the dark art (I beg pardon), photography.

Having done so, however, he went ahead conscientiously, as he considered, and laid down a theory which no one can very well upset, namely, that a photograph is a photograph, and that naturally the placing of any of the qualifying words, perfect, good, or artistic, before same would not in the least alter the conditions. There is one thing very certain, that, if being *thorough* constituted virtue, we might look upon him as the most virtuous photographer of our days.

His rival was not what we might call, strictly, an artist, but he was a very sound, practical photographer, and although he could not paint a likeness, was a very good judge of one when it was placed before him. He possessed an aptitude for posing gracefully—indeed, if we may be a little liberal to him, we may consider him an artist without the artistic training which might have enabled him to assert himself without the aid of his camera. In his ideas he was liberal to a degree; there was nothing new he would refuse a trial to, and honestly give it a fair chance of gaining favour in his eyes. Shrewd to a degree, he knew at a glance what a customer wanted, and went the best way to produce it. This will be enough to give us an idea of the two gentlemen whose dissimilar sentiments as photographers form the bases of these few lines.

It was a lovely morning in early spring, one that brings gladness to the photographic heart, one that prompts the multitude to exclaim, "What a glorious day! I'll have my photograph taken." And off they go. On such a morning some time ago a poor wretched soul, evidently not too well treated by Dame Fortune, came trudging down the street in which our rival friends had their studios. He was on the side of the artist photographer, not the photographer artist. At sight of the two show-cases on right and left of him his eye seemed to brighten, and he pulled himself upright, and, getting closer to the show-case, took a look, and thought to himself, "There is a chance here for me." He was a poor, wretched retoucher, and must really have had the sympathies of every one—that is, *every one* who was not a photographer.

Pulling himself together, he walked upstairs and asked to see Mr. A., and was told by the lady in attendance that he was engaged at the moment, but if he would wait, &c. "If he would wait!" it was a case of "would a duck swim?" So while he was waiting, he took a good look round. The studio was beautifully appointed, but somehow it did not look as if the entire business of the town was done there. There were some very excellent *photographs* around the room, but he marvelled in his benighted innocence that there was not one of them retouched. While he was wrapt in thought (evidently tearing his bewildered brain to know why this was thus), no doubt some moments must have passed unobserved. Suddenly a footstep was heard in the adjoining apartment which rudely brought him from "the land of dreams" to the stern reality of a photographer's studio, and a retoucher out of work.

It was no longer a question of "Why is there no retouching done here?" but "Will I get a crib?"

No sooner had he propounded to himself the latter question, than Mr. A. walked slowly, and with no small degree of majesty, into the waiting room. Somebody's blood *had* to freeze, and Mr. A.'s wouldn't. Nevertheless, advancing to our frozen friend, he most politely inquired, "May I ask why I have the pleasure of this visit, and whom I must thank for it?"

There was nothing for it but a bold front. It was the old battle-

cry of thousands before him, "Victory or—no dinner!" So summoning up all the courage he had about him at the moment, he replied, "I was passing through the town looking for work, and thought, *seeing the specimens outside*, that there might be an opening for me in your studio."

"Are you a photographer?" was Mr. A.'s only reply.

"No, I am sorry to say I am not."

"An artist, then—in oils or water colour?"

"I do not paint, but —"

"Not a photographer!!! Not an artist!!!"

I have only a small dictionary beside me, and I am unable by it to find words adequate to paint the amazement, no, bewilderment, of Mr. A., at the idea of my friend thinking there was room for such as himself. After a pause (evidently Mr. A. had failed to divine the reason why his visitor came beneath his roof) he very coldly asked, "Since you are neither able to photograph or paint, may I ask in what capacity you fancied I might require your services? What are you?"

At last the crucial moment had arrived, further disguise was useless, the dreadful truth must out. So with what courage remained (and, by-the-by, it was precious little) he confessed, "I am a retoucher!"

It is a lasting pity that there were not at least ten thousand people within eyeshot to see the smile that radiated over the countenance of Mr. A. at this damning declaration. You must not think it was one of bitter contempt—no, he would not be so cruel—it was one rather of supreme pity. I want every one to thoroughly understand that, although he would not, on any account, give him half-a-crown for retouching a large head, he would not be so mean as to deny him the pity due, by right, to a retoucher.

The shock was indeed mutual, and both were slow to recover from it, but Mr. A., reviving more quickly, resumed the conversation.

"Young man! Look around my studio. Do you see a single photograph there which has been sullied by the plumbago of a retoucher's pencil point?"

The poor devil looked around, but did not see *one* that had been retouched. All the same, though, he saw *lots* that would have been better if they had been.

"No," he replied, "there is not one that has been retouched."

"I should think not, indeed! Photography is an art, and far above the paltry help a retoucher would fain bestow upon it. Photography is truth and truth, the least interfered with, is best. I am very sorry, but really I cannot avail myself of your services. Good morning!"

Turning on his heel he went over to one of his larger photographs on an easel and fell hopelessly into an ecstasy over one of his own specimens. There was nothing left for the retoucher now but to *get out* as gracefully as he could, so wishing a polite "good morning" to the artistic photographer, he departed on his weary way, and, no doubt, through lack of appreciation, felt somewhat of a prejudice. Although I naturally take a great interest in him, I will not follow him just now, but rather pick him up later, as I know where he went on leaving. I also wish to take up my quarters at Mr. A.'s studio at least for a little while.

The lady who first received the departed visitor returned almost immediately he had left, with some work to be examined by the proprietor. While looking over it, he said, "Really, Miss S., I am astonished at the numbers of misguided men who spend their time spoiling the perfect products of the photographer. Thank heaven! I have never fallen into such errors like so many of my neighbours. What can photographers be thinking of to employ such men? What can the public be thinking of to prefer the retouched pictures to the pure and simple photograph?"

He handed her the work back and she went her way. Judging from the manner of her going, I fancy she had heard remarks of a similar nature before. Having finished his contemplation of the plain photograph, he went to his easel upon which he had an unfinished portrait in oil. But before he was many moments at work an elderly country gentleman and his daughter came in and wanted to be photographed. They were simple folk, and were somewhat over-awed by Mr. A.'s very imposing manner.

"You wish to be photographed?"

"Yes," said the father, "I and my daughter. I am not so very particular about myself, but I want a good picture of my little darling. I think I would like a large head of her as well."

"Certainly, she has very finely marked features and should make a very pretty picture."

"Yes," rejoined the proud father; "she is looked upon as the beauty of our parts. Now, Mr. Photographer, above all I want a *likeness*; none of your fashionable beauties for me, but her simple

self. She is quite beautiful enough, although I say it, perhaps, as shouldn't."

"I am an artist, sir," said Mr. A., "and the trickeries which ruin so many pictures have no place in my establishment. Truth is what I aim at. Photography pure and simple cannot err."

"That's good."

"Will you kindly step into the dressing room, and I will send for you in a moment. Your daughter can arrange her hair. She will look best with her hat off."

Father and daughter go to arrange the necessary touch-up, before the dreaded ordeal of being *shot* by the camera, and Mr. A. to see after his assistant and get the plates in readiness.

It was quite refreshing to hear this old gentleman talk. Of photography he naturally knew nothing, so we need not pay much attention to his remarks. He was a fine old fellow, however, the picture of health. His hair was almost white, his forehead very fair, and the lower portion of the face the picture of health. He had a rather strong complexion—deep and ruddy. His daughter was a most striking girl. Lovely auburn locks, to be slightly complimentary; a skin as fair as snow, but as is often the case, very badly freckled.

In fine, I must say they were two subjects that would give "fits" to a retoucher, and would try his patience and skill very considerably to do them justice. A pang of doubt might even cross the mind of the photographer who employed him as to the result. This, however, to an artist of the calibre of Mr. A., was child's play. His lens could not fail to reproduce nature as it was. There would be no risk of losing the likeness by any reckless laying on of the "retoucher's plumbago." No; it would be pure art—photographic art! as we will see when the proofs come home in the course of the next week.

REDMOND BARRETT.

(To be continued.)

CARD-MOUNTED FLEXIBLE GLASS FILMS.

[A Communication to the Birmingham Photographic Society.]

ON a previous occasion I had the pleasure of drawing the attention of our members to my flexible glass films, and I then pointed out the importance which, from the earliest practice of the photographic art, had been placed on the medium carrying the negative as affecting the results.

A matter of not less importance in these days of haste and impatience is the production of a negative which will print quickly and be equally suitable for the production of either paper or glass positives, or for enlargements; these conditions are more perfectly obtained on my flexible glass films than on any semi-transparent medium.

The drawback to the use of these films has been that they were not quite ready for use, also that they were much more costly than glass. I now send the films out quite ready for use by attaching them to cards strong enough to hold the film in the camera flat and true. When it is desired to develop the latent picture the film is drawn from the card and placed in the developing dish, and treated in all respects as if it were a plate. Recent improvements have made the supporting medium free from any tendency to curl or twist in the developing or fixing processes.

Plain Mounted Film.—Here is one of the card-mounted films. I will release it from the card, and, had it been exposed in a suitable light, it would now be ready for development. The only other point requiring attention in the working of these films is the method of drying, which has always been the weak point with films. The plan which I now give has been well proved, and is in all respects satisfactory, and produces a negative as flat and true as a glass plate.

It consists simply in pasting the negative upon a stiff cardboard to dry; the card allows the paste to dry from the back. The film itself being impervious to moisture cannot be dried on a glass plate. The varnish is applied when the film is dry and before it is removed from the card.

Directions for Drying.—When the negative is washed it is placed face downwards, all moisture is removed from the back, and it is then placed on a piece of thick cardboard which has been evenly but not thickly brushed over with paste, and the negative well rubbed down to exclude bubbles; this may be done either with the hand, or a piece of paper may be laid upon it and rubbed. It is then allowed to dry, which will take ten or twelve hours. The paste used is made by mixing one ounce of flour with six ounces of water until perfectly smooth, then boil it and use when cold.

Varnishing.—This is an important point and should not be omitted, as it prevents the film curling by the gelatine surface absorbing moisture.

When the surface of the film is quite dry, apply the special varnish (cold) with a soft brush; it will dry in two or three hours. The brush should be kept soft by being placed in spirits of wine when not in use.

I have here several negatives and pictures printed on the films, some of which are at present attached to the drying cards and have been varnished and are ready for lifting; having done so, I shall then have showed the process from beginning to end.

A. PUMPHREY.

TREES AND LEAVES.

THERE is, perhaps, nothing that has more influence on the effect of the landscape than trees. Trees from the earliest periods have figured largely in pictorial compositions. The conventional tree, like a Chinese pagoda or a bunch of shavings on a pole, has gradually given way to more truthful representations, until by photography we have the most minute rendering of every bud and leaf, branch and tendril, this realistic picturing admitting no doubt of the kind and species of the tree, whether the familiar ash or the lordly cedar. In drawing and painting, trees are now rendered with fidelity to nature in the arrangement of the branches, massing of the leaves, and general effect, the impression conveyed being truthful and satisfying. It remains, however, for photography, in addition to and without impairing these qualities, to add that of infinite detail, such that no human hand could give, and without in the least destroying artistic effect, or the massing of the lights and shadows.

Trees by themselves, alone, will often make very beautiful and effective pictures, either in winter, with their bare and interlaced boughs sparkling with hoar-frost, or in summer, with their full robes of greenery, through which the sunlight flickers, changing their sober greens to emerald and gold. What variety and contrasts are continually offered to our artistic observation by masses of foliage, from the gloomy pine wood on a lowering day, to the sparkling lights on the silver beech on a summer afternoon. Trees have always been, and in all probability always will be, somewhat of a difficulty to the photographer. Many an otherwise good picture has been ruined by the movement of the leaves and branches, and I may safely say they have not always been looked upon as blessings, even in disguise. Oftentimes this blurring effect may, not unfairly, be attributed to want either of skill or patience on the part of the photographer. Trees are generally looked upon as mere accessories to the landscape, just thrown in for the sake of effect, without any further consideration. Now, I fancy, if we sometimes reversed matters and considered the trees, throwing in the landscape for effect, we should do wisely, and secure many a beautiful picture we now pass by.

The subject of trees has scarcely yet been treated exhaustively by photography, although many a treatise has been published to aid the draughtsman and the painter with sketches of the foliage and ramifications of the branches, which could be infinitely better done by photography, which would, in affording aid to others, demonstrate its own pictorial efficiency. In photographing trees and foliage it is important that the light falls in a suitable manner, and that light and dark portions are nicely contrasted; a branch strongly illuminated and clearly defined, relieved against the darker or receding portions, will at once proclaim the kind of tree it is, acting, as it were, as a key to the mass of surrounding foliage, and at the same time enhance its pictorial effect by preventing that spottiness which so often mars subjects of this kind. Unless a tree particularly lends itself to photography by its form or surroundings, the best effect is obtained without direct sunshine, this being reflected from the shiny surface of the leaves in much too strong a manner for pleasant effect, causing spots of light that require considerable care and attention to harmonise. The brighter the sunshine the longer the exposure in most cases, the reason for which is easily understood, as under such conditions the shadows become more non-actinic, not only by stronger contrast but by the additional aid of the colour of the light transmitted through the substance of the leaves, which is, in a great measure, absent in diffused light. The contrasts being reduced by the weaker illumination, a shorter exposure may be given. Foliage, perhaps more than anything, is reduced in actinism, if I may so express it, by a bad yellow light, so that it is much more difficult to get a proper exposure of it than of other objects under similar conditions. This opinion, is, however, subject to certain qualifications, as the kind and position of the tree has considerable influence. I should say that a tree in a bad light would require at least twice as long exposure as a building under the same circumstances, to obtain a proper amount of detail in the shadows and a good quality of negative.

I am somewhat doubtful if local colour, in the case of trees, has much effect on the results. There is no doubt that local colour on

other things has considerable photographic effect, for by comparing photographs of red sandstone and limestone it is readily noticed; but with foliage, each leaf presenting a different angle to the light, the reflection overpowers local colour. In proof of this, take a photograph of an ordinary beech or other green tree and compare it with one of a copper beech, whose leaves are deep maroon red, of a very non-actinic colour. The same exposure in good diffused light will give equal detail in each, so that it would be impossible to say from the photograph the colour of the foliage varied. The principal reason that foliage requires a somewhat longer exposure than other objects is, I take it, because of the abruptness of the lights and shadows, especially in those trees with shiny foliage, such as ivy and holly, which a long exposure harmonises. If photographing in a wood or thickly embowered lane, the conditions are similar to photographing an interior, and the exposure will be much the same; the same precautions must be taken to prevent blurring and halation as when the light comes through the windows of a building and is included in the picture—in some cases the contrasts are even more trying.

Of all trees with which I am photographically acquainted, the yew is least amenable to treatment. If such a tree occurs in a well-lighted, open landscape it will be rendered as a blot, with little or no detail, so little light is reflected from it. Some kinds of pines are difficult to render for the exactly opposite reason, tufts of light-coloured leaves standing upright reflect the light so that the effect of blurring is given; but, fortunately, neither one kind or the other very often occur in general landscape work.

The tree of all others that lends itself to the requirements of photography is the plane; the size and disposition of its leaves are very effective. The sycamore is of a very similar character. Both trees are frequently associated with buildings, rustic fences, the odds-and-ends of agricultural requirements. The elm and ash both enter largely into the composition of an English landscape, the elm being a very effective mid-distance tree, more varied in outline than most others; but for a near view the smallness and roughness of the leaves produces a somewhat indistinct and spotty effect. The branches are themselves picturesquely arranged and grow low down on the trunk.

The willow is a most effective foreground tree and flourishes in moist situations; it is usually seen by the side of rivers and water-courses, and frequently in a state of picturesque decay, the split and hollow trunks having a character entirely their own, lending themselves well to the requirements of the photographer. If we examine the cattle pieces of Lee and Cooper, and many other painters, we shall find the willow forms a very important feature in their pictures, it more than any other tree indicates the character of the ground on which it luxuriates. Meadows and streams are usually associated with it, and as is frequently the case, the soil having been washed away from its roots, the tree, or part of it, hangs over the water and is reflected in it, suggesting to the photographer the probability of an effective picture. The chief drawback is the tremulousness of the leaves and the frequency of their movements, chiefly owing to their habitat, for on the banks of streams currents of air are almost always in motion. The black alder is another of those trees to be found on river banks, and is also one of the most picturesque, growing to a good size in favourable localities, although it will dwindle to a mere bush on the uplands. The foliage is rather dark in colour, but fairly rigid, regaining its original position soon after the breeze has passed, an estimable quality photographically speaking. The branches are picturesquely arranged and are eminently suitable for tree studies. The Oak is perhaps one of the most picturesque trees of all, either with or without foliage, and seldom fails to compose well. The rigid character of the branches and short leaf-stalks are less influenced by wind than most trees, and for these reasons recommends itself to the photographer. It is a very widely distributed species, and varies greatly in dimensions according to its habitat, from that of a mere shrub to one of the largest forest trees. Bracken and herds of deer are frequently associated with it, as, like the Beech, it affords a welcome protection from sun and storm. The Beech is one of the trees, and almost the only one, that photographers have frequently made pictures of on its own account, and most are familiar with photographs of those of Burnham, both in and out of leaf, and very pleasing subjects they afford. The Elder tree, or as it is more frequently seen not more important than a bush in size, is still effective and useful photographic greenery, the foliage being distinct and characteristic; but when in flower it becomes too spotty to be very much use, the large patches of aggregated blossoms of a cream colour looking much too uniform for pictorial effect. This tree is mostly found near to dwellings or in the hedgerows of cottage gardens, and is very suitable in the composition of rustic bits.

From trees we now turn our attention to foreground plants, upon which so much of the beauty of this portion of the picture depends, and which, in many cases, will metamorphose an uninteresting into an

artistic picture. The Dock family contribute largely to this, and, take them altogether, are perhaps the most useful of this class of plants. The large, broad, bold foliage supplies good light and shade effects; the shape of the leaves and their arrangement leave little to be desired. The Hemlock and Foxglove in their season are most artistic and useful; the white umbellate inflorescence of the Hemlock often is of infinite use, its light, deeply-cut leaves standing out well from the surrounding vegetation, and may almost be said to be the making of some roadside studies. The coltsfoot is good for a light foreground, the rough, large leaves reflecting a considerable amount of light. Regarding climbing plants, the common nasturtium is perhaps best of all in cottage scenery; trained over the fence or up the plastered walls it is of a most decorative and picturesque character. The Clematis is also a useful plant, trained, as it often is, over the trellised porches, and growing in wild luxuriance forms excellent subject for picture making. Foreground plants are not photographed nearly so often as they ought to be, for their own sakes, although a well chosen subject of this kind is very fascinating. The material may be commonplace and simple, but the skilful photographic rendering of them is exceedingly beautiful, and commends itself to those possessed of artistic feeling, offering opportunities of picture making often neglected. The points to be remembered are that the best effects are obtained in strong diffused light, and should be rendered on a tolerably large scale. An undoubted advantage is, such subjects are plentiful, most hedgerows supplying the necessary material.

As to ferns, they recommend themselves; a good study of them, with a few rocks or boulders, compose a picture artistic and satisfactory, with a minimum of trouble. All subjects of this kind are better taken with a long-focus single lens, and from a near point of view.

There are many other trees and plants not alluded to in this article that materially assist the photographer to make pictures, but those indicated are the principal ones to which he may specially turn his attention with a fair chance of satisfying himself and affording pleasure to others.

EDWARD DUNMORE.

UNEMPLOYED PHOTOGRAPHERS.

THE prevalence of unemployed photographers is largely connected with the subject I recently considered in these pages, of the amount of average education of the dwellers in these islands and the relative superiority of average education in the more civilised nations of Continental Europe. A passing remark was made by me that some schools, much patronised by the English, are established in Guines, not far from Calais, but I said nothing as to their quality, because I knew nothing upon that point. An anonymous correspondent has since publicly stated that he was sent to one of these schools when a boy, and that the education given therein was worthless, but that in French Government schools a good education can be had. This shows the necessity for having nothing to do with foreign private schools without careful inquiry beforehand. Within our memory, the state of education in England was once such that the man who had failed as a footman, railway porter, and dust-cart man, as a last resource took to educating British youths, after which he lived, more or less, upon the fat of the land. There is nothing to prevent such a man picking up a little French and starting an English boarding school upon the other side of the Channel. There are good private schools abroad; some are scattered in remote French agricultural districts, and are patronised by English families who know exactly what they are doing. The difference in the cost of living between England and France enables the proprietors of the schools to board and educate children at a cost not much above that of their mere keep in England, and the scholars have the advantage of learning French in the country in which it is spoken. Still, the safest plan for those who know no such schools is to take care to select one the efficiency of which is guaranteed by the imperial or local public authorities. As already stated, I think about the best place very near England in which to select some such school is Ghent. The Straits of Dover were first crossed in a balloon on the 7th of January, 1785, by Jean-Pierre Blanchard and by John Jeffries, an American. The latter was the son of the David Jeffries, Treasurer of the city of Boston; he was educated at Harvard University, and obtained his doctor's degree in Scotland at the University of Aberdeen. They crossed the Channel at a low elevation, and came down in an open glade in the Forest of Guines. The feat caused immense excitement, and the spot at which they alighted was marked by a column in their honour. This monument had been gradually much defaced, according to the natives, by French cows and by English schoolboys from Guines; it was accordingly restored two years ago, and a week later I not only met English schoolboys in the forest, but found the newly restored monu-

ment inscribed in pencil with such names as Smith, Brown, and Robinson.

Coming now to the subject of unemployed photographers, a good education in early life is one of the safeguards against want of employment; but England, as compared with some great foreign nations, being an uneducated country, we must unfortunately take the facts as we find them. Most of the unemployed persons I have met in life have been in that condition entirely through their own fault, and have in no instance been willing to admit that such is the case. Many of them have been too ignorant or too lazy to learn a skilled trade or profession, and unskilled labour naturally goes begging all the days of its life. The whole tendency of the times is to lower the demand for unskilled labourers; such persons should either make themselves skilled workmen or emigrate, to do any rough work they can get on farms on the outskirts of civilisation. The world is a great market; the man who wants employment should carry into that market some skilled labour which the world wants to buy; if he lazily enters it with unskilled labour, he has nobody to blame but himself when he finds no purchasers. Hence parents should not make ordinary clerks of their children, or put them into a trade in which they are mere counter-workers, selling to one industrious person what another skilled labourer has made; such unskilled shop-assistants can be replaced by almost any one in twenty-four hours, but a skilled worker is not usually so easy to replace. An intelligent skilled artisan who works with tools usually has a life much more free from care than a city clerk, and is in a more independent position.

A young man who intends to improve himself in some direction as hereinbefore suggested, should not consult his companions as to the wisdom of his intention; for he then appeals but to the average intellect, which always seeks to drag down any aspiring mind to its own level, and to throw cold water upon new ideas and exceptional individual exertion. In cultured society this is not so much the case.

Average photography is not now such a skilled industry as it was in the old wet-plate days; the advent of dry plates has made it much too easy, and has brought into the field also a flood of amateurs. First-rate photography is a skilled industry, and its followers are comparatively few; they are good artists, quite independently of photography; they possess technical knowledge as well, and are experienced in the ordinary routine work of the profession. Mere average photographers have not now very brilliant prospects, though there may be exceptional cases; the average assistants of average photographers are in a still worse plight, and when out of employment may not always find it easy to get into it again. Yet do they blame themselves for this? Not a bit of it. Frequently neither master nor man makes any attempt to practically educate himself in the higher stages of photography, yet he blames the world because it will not pay for half-skilled labour, of which it already has too much. Why should it buy what it does not want?

Six months' want of an engagement ought to be a blessing to a photographer's assistant who properly uses his time. He should spend several hours a-day in learning drawing, painting, and the accepted canons of art, more especially as regards posing and grouping; at the end of that time he should be skilled enough to carry out Mr. Nisbet's plan, of sketching with a bit of charcoal in a few minutes a background to suit the appearance and occupation of any particular sitter. Then let him apply for employment, and he will at once find the advantage he has gained over some less skilled competitor. As time goes on he should make himself an artistic retoucher as distinguished from a mechanical retoucher; he should teach himself optics, and the mathematics and principles of construction of lenses, and be able to test and express in accurate figures the working powers and characteristics of any lens placed in his hands. Having mastered these useful branches of his subject, at the simple expense of giving the time and buying a few second-hand books, he will find himself such a different individual, quite apart from any changes in his commercial position, as to have acquired a thirst for knowledge; he will take up other branches of self-education, and explore for himself "fresh fields and pastures new." Much the same advice may be given to his employer, who, with his income going down and his rent going up—people usually in this exceptional country not being their own landlords—has the poorhouse or emigration looming in the distance. In London, for instance, leases of business premises are getting shorter and shorter, and tradesmen are even gradually being turned into but yearly tenants, laden with enormous premiums and increases in rent; so the time seems to be approaching when nothing whatever of the fruits of their labour will go to themselves: not that they get much now—the chief Continental nations are too intelligent and well educated to permit any such system, and they are well aware of the different position of the English populace. Civil and other paid ser-

vants of the nation setting up in trade add to the acute nature of the home position, so that sooner or later a collapse of some kind is, by natural law, inevitable.

A man out of employment who does not utilise his time in making himself a skilled workman, is not alone doing no good to himself but is doing injury to others; he is in a reprehensibly false moral and religious condition, because he is living upon the industry of other people, and adding to their burdens, for he has to be kept either by his friends or by the parish. In Belgium such paupers are placed in establishments under the rule of the military, and are forced to learn a skilled trade. Some of them dislike making themselves skillful workmen so much that it is found necessary to put soldiers over them to make them work. In the end they are turned loose with much less excuse for living upon the industrious than they had when they were taken in hand by a wise government. W. H. HARRISON.

THE ASTRONOMICAL CONFERENCE AT PARIS.

THE astronomers who met together on the 16th ultimo at the invitation of the Paris Academy of Science have, after sittings extending over eight days, agreed upon a plan to be generally adopted by the various observatories which will join in the work of making a photographic chart of the heavens, with an accord that promises well for the complete success of this most valuable work.

The first meeting took place on Saturday, the 16th of April. The proceedings began by an introductory address by M. Bertrand, Secretary of the Academy of Science. M. Flourens, the Minister for Foreign Affairs, then gave an address welcoming the astronomers in the name of the French Republic. This address was responded to by M. Struve on behalf of the astronomers. The conference then proceeded to elect officers, choosing as President Admiral Mouchez, the Director of the Paris Observatory; as Acting President of the Conference, M. Struve; as Vice-Presidents, MM. Auwers, Christie, and Faye; as Secretaries, MM. Tisserand and Bakhuyzen, assisted by MM. Duner and Trépied. The Conference then took into consideration the main questions, and agreed upon them after some discussion, those main questions being briefly—1. The need of a photographic chart of the heavens; 2. The use of instruments alike in all their essential parts; 3. The extent of the work generally.

A committee was then formed to consider the kind of instrument to be employed. After considerable discussion this was decided to be an instrument identical with that already employed by the Brothers Henry in Paris, the magnitude of stars to be taken on the photographs being fixed at what is now known as the fourteenth magnitude.

After the report of this committee to the general conference, two sections—the astronomical and the astrophotographic—were formed to consider the minor questions under each head. Those sections presented their reports to the general conference on Saturday, the 23rd. They were, with some little modifications, adopted, and the conference met on Monday, the 25th, to appoint a permanent committee to direct the work while in progress. The committee named by the conference for this purpose consists of all the directors of the observatories taking part in the work, with a certain number of members not necessarily actually engaged in this work.

The conference nominated Janssen and Common as a committee to consider the application of photography to other celestial bodies not included in the scheme of a photographic chart. The exact text of the various resolutions is not yet printed, but the result of the deliberations of the conference may thus be summarised: A photographic chart of the heavens is at once to be undertaken by the various observatories which will join in the work, with instruments practically identical with that made by the Brothers Henry, but of course not necessarily made by them. The limit of the magnitude to be obtained on the plates, which are to be in duplicate, is to be that known as the fourteenth. In addition to those plates, which will require an exposure of about twenty minutes, another series of plates will be taken, with a very short exposure, in order to obtain the brighter stars with smaller discs, so as to make the exact measurement of those stars more easy. The methods of work are to be as nearly as possible the same. The minor questions, such as the extent of field to be photographed, the processes to be employed in making, developing, and preserving the plates, and all other questions of practical importance, are to be decided by the permanent committee already named.

The result of the conference is therefore a practical scheme for doing this work, and in deciding thus to follow only the results that have been proved by the Brothers Henry to be thoroughly practicable they have put the matter on a very secure footing, and have left nothing doubtful as to the actual possibility of doing the work well and, if a sufficient number of observatories join, in a very few years.

Difficulties will be met with, as they always are in such undertakings, but the conference in thus keeping clear of all experimental or unproved plans has done much to make those difficulties as small as possible.

Six observatories, four of them French, have already joined, and Chili, through its Ambassador at Paris, has declared its intention of joining; there are thus already seven observatories which will at once, when the instruments are ready, begin the work. Many of the astronomers who

attended the conference stated that, while they were unable to say definitely that their Governments would join, had little doubt that they would do so; so that now it may be considered as finally settled that we shall soon have a photographic chart of the heavens, the value of which it is quite needless to speak of. The arrangements made for the work of the conference were most complete, and reflect great credit on Admiral Mouchez and the French astronomers. The proceedings throughout the whole of the eight days during which the conference sat were marked by an amount of good feeling that is not always found in scientific gatherings. Though many of the questions were discussed with great vigour, the voting, when the matter was voted upon, was in nearly every case unanimous.

—*The Times.*

WHERE I WENT WITH THE CAMERA.

No. V.—NIJMEGEN.

NIJMEGEN was the next place of interest that I visited. This town bears upon its front the impress of antiquity. Here Charlemagne lived in 800, and at the Valkhof the remains of an old heathen chapel stands, said to have been built in 799. On the little hill where this chapel is situated a charming view of the river and town is obtained, but from a photographic point of view I found it useless, the subjects being too distant to give anything like effective pictures, and the foreground filled with foliage from the tops of the trees that grow on the hillside. The tips of stray branches of these would come in front of the lens, and yet they were growing at too great a distance to be got rid of, thus spoiling the effect of any little bits I might have managed to get. I followed the next best course, and descending to the level, took a picture of the hill and ruins from the riverside.

Coming out of a narrow street upon the market-place, I was at once thrown into the noise, and bustle, and life of the town. The centre of the market-square was filled with stalls, each loaded with fruits and flowers, the attendants wearing costumes of many hues, and bedecked with ornaments peculiar to that part of Holland from which each came, the houses on the four sides towering up six or seven storeys high, with fronts all painted and decorated. Colour, colour, colour everywhere; colour from the fruit, colour from the flowers, colour from the stall-keepers' dresses, broad patches of colour all over the house fronts filled the eye, and produced a picture brilliantly dazzling in the sunshine. I took a photograph here, but it was not very successful, for the crowds came about in hundreds before the camera was an instant up. Seeing my "fix," a young lady came out of a shop close by and told me that if I waited half an hour most of the people would be away to their work again. I had unfortunately come upon them during their dinner-hour. I thanked the young lady for her kindness, but when I got back the market was over, the sun was down, the opportunity was lost.

Going into the centre of the market-square now all was quiet, and looking up and around, I felt as if I were standing in the middle of a huge packing box with ornamental sides. There was a stage-property-profile effect about the whole arrangement that many of the streets and houses here had impressed me with. Of a far more solid type was the next place of interest I visited. Up from the market-place a short distance, in its venerable quietude, I came upon the Stad Huis, or Hotel de Ville. It had stood there stolidly holding its own, seemingly unchanged, for hundreds of years, looking down on the ever-changing groups in the living passing show that moves on continually, giving place to new men and new things, each in their turn being blotted out and forgotten.

This house with a history holds within its walls relics of every kind, gathered together out of the past, each with a story all its own, forming a chain of eventful records linked together, completing a history that can be traced back to the borders of antiquity.

Inside this house the same old man repeats that same old story day after day, until one morning he too will have passed away, when another will take up the burden of the oft-told tale, and run it during his little time, when he also will leave it to another, the house only remaining seemingly unchanged.

The collection of curiosities in this Stad Huis was the most unique and antique of any I had the pleasure of seeing during my journey. There were tapestries, old coins, banners, trade flags and badges, old armour, paintings, municipal decorations and gifts, instruments of torture; and, by the way, regarding these instruments of torture, one remarkable feature in connection with them was that in all cases they had been used for punishing women only—unruly or unfaithful wives. In those days the men must have been very, very good, for there was not one appliance on view that had been used in bringing back the erring men to the right road; hence the supposition is that they never left it. "Oh, for the good old days!"

The collection of old silver curiosities in this place was wonderful, even for a town in a country famed for its abundance of marvels in silver. In illustration of how much such collections are valued and guarded, I heard a good story on my way. I will give it you here. The young gentleman who told me the following story was a Jew, and one of the principal actors in the comedy, so he gave it in telling all the little touches that made it a very enjoyable tale:—

"Yes, sir," he said, "talking about that old silver, they put such a value upon it that money can't buy it. I remember once when I tried to

negotiate a sale. We were in that trade you see, and a gentleman called on my father one day to get his assistance in buying some old pieces of silver that he had seen and coveted. This silver was held in safe custody by the burghers in a small out-of-the-way town that shall be nameless. 'Will you come and help me to buy it?' the gentleman asked.

"I fear you will not be able to procure it," my father replied.

"Never mind," said the would-be buyer, impatiently, 'let us make an attempt at any rate. I want you to go with me and negotiate.'

"I am far too busy just now," my father said, with a smile and a shake of his head; 'it would be quite impossible for me to go, but I'll tell you,' he said, turning to me—I was then a lad of about eighteen years of age—'little Jules there will go with you.' When he saw doubt expressed in the gentleman's face, he continued, 'And, believe me, he will do the business for you quite as well as I could.'

"All right," said the gentleman, still looking incredulous; but he patted me on the back, and said, 'Be ready to start with me to-morrow.'

"Very well," I replied, and on the morrow we travelled to an out-of-the-way little town about a hundred miles away from my home.

"After the silver had been carefully examined by our client, he proposed to me to buy privately, if possible, some special lots that for pattern suited sets that he already possessed.

"I called upon the man in authority and placed my proposals before him, but I was very quickly snuffed out. 'No, no, sir; we could not sell the silver,' was the reply given in a high and mighty tone. 'It is the town's property, and dare not be touched.'

"But it is only a few pieces we want, they never would be missed."

"No matter, if it were but one piece it could not be sold."

"We will give you any price you like to name for it," I insisted.

"No price would tempt us; it's the town's property, and we cannot sell."

"So I returned to my employer and told him of my defeat.

"We knew that as a corporation they were hard up, but we did not see how we were to make any headway; however, we arranged to stay all night and see if I could resolve on any plan for the next day. We had an early visit from the custodian of the silver in the morning, and after the usual greetings he came to business at once by saying, 'I think that I see my way to get my brothers in office to part with that silver.'

"How?" exclaimed my employer eagerly.

"Well, you see, we are in want of a fever hospital for the district; if you offer to build it I will arrange that the silver is handed over to you as a small return for your kindness."

"But what would be the cost of building an hospital?" asked the would-be purchaser, dubiously.

"It would take some six or seven thousand pounds," replied our visitor, cheerfully, as if that was a sum of no moment.

"Oh, that's arrant nonsense!" replied my client with a sneer, and, turning on his heel, closed the conversation by saying, 'We will think no more about it, sir.'

"Our negotiations were a failure, and we left the place by the midday train."

"I had quite forgotten all about this visit for some years, when it was brought to my memory by being again called to the same town on business. This time it was to value some paintings and other articles of *vertu* in the interest of the German Government, this place in the interior having come under the jurisdiction of the Emperor.

"As I was descending from the train I caught sight of a Mr. Isaacs at the station, and he being in my own line of business I wondered what he could want there, when all at once I hit it, and said to myself, 'It's that old silver.'

"So up I goes to my friend, and without any preliminary I said, 'Look here, Isaacs, I know what you are about here. You're after that old silver. But mark what I say, you will never finger a little piece of it unless you agree to go shares with me, for I had a deal of trouble and no profit over the same thing some years ago, as you know.' I ventured to assert that he knew it, for I was sure if he was on for that silver the buyer was the same man. Isaacs only laughed and showed his teeth, but would give me no promise to share with me.

"I knew that my wealthy client sometimes employed Isaacs, so I set to tracing up their whereabouts in the town, and found that they were both staying at the same hotel. Having obtained this information I quickly set about doing my own work for the Government, which did not take me long, and then set to to trace out that transaction of Isaacs'. And would you believe it, sir, the negotiations were just about closed, and the sum that was to be paid for that silver was forty thousand pounds. Oh, I was wild! Just fancy such a slip! But I determined to put a spoke in Isaacs' wheel at any rate. Without delay I telegraphed to Berlin that the corporation here were disposing of some valuables belonging to the town collection worth forty thousand pounds, and that the matter should be looked into at once. And there was a considerable commotion in the town that afternoon, I can tell you. Of course I kept in the background, and was never seen. But I had the pleasure of seeing Isaacs and my former client leaving the place next day, carefully, though secretly, watched by Government officials, who had told them that their immediate departure would be considered necessary. And that was what Isaacs got by being too sharp, and playing down upon me so.

"The German Government bought up the silver and gave the full value for it, so my friend will never have the chance of buying it now until they

are selling off the German Empire, which won't be in our day, I fancy."

In the smoke-room of the hotel I heard this story, and it was told with all the air and sincerity of truth.

Two or three very pleasant days' work will be found for the camera in Nijmegen. After exhausting the streets, many of which are very picturesque, prominent points, such as the Belvédère, Kronenburger Park, Valkhof, &c., will be found worthy of attention. I got some good panoramic effects of the town from the other side of the river, and charming pictorial effects are to be had on the river itself all day long. Next I went on to Berlin.

MARK OUTE.

AMERICAN CORRESPONDENCE.—W. K. BURTON IN NEW YORK.

It may be of interest to many of his friends at home to learn of Mr. Burton's safe arrival here on the 16th, and of his efforts at sight-seeing. He has met with a very warm reception by both amateur and professional photographers, who are not only pleased but surprised to find in him a man of a youthful and vigorous appearance, quite practical and American in his manner. He spent an evening at our New York Society club rooms, and was agreeably surprised at the large size of the premises and the various kinds of expensive apparatus kept there for the use of members. It was all on a larger and more business-like scale than he had anticipated. He was entertained with a short exhibition of lantern slides, and found several of them were of a superior quality.

On Thursday evening, the 21st, prior to his departure for San Francisco, upon the invitation of our new and genial President, Dexter H. Walker, a few members of the Society and their friends, together with the officers, entertained Mr. Burton to an informal dinner at the St. Dennis Hotel, corner of Eleventh-street and Broadway. Every one was in the best of spirits, and as a result the evening passed very pleasantly and profitably to all concerned. Unfortunately President Walker was unable to preside because of a sudden illness, and Dr. John H. Janeway, our ex-Vice-President, was prevented from attending in consequence of a previous engagement elsewhere. Vice-President George A. Allerton presided, and Recording Secretary Daniel P. Read assisted at the opposite end of the table. Among the others present were W. I. Lincoln Adams, of the *Photographic Times*, Arthur H. Elliott, of *Anthony's Bulletin*, George H. Ripley, William M. Frisbie, Thomas T. Eckert, jun., and myself.

Several toasts were offered. Mr. Allerton and Mr. Read both heartily welcomed Mr. Burton, extending to him the good wishes of the Society. Mr. Ripley spoke of having been first interested in photography through a small item written by Mr. Burton published in the *Photographic Times*. He commended Mr. Burton's writings, was always interested in reading what he had to say, and invariably evolved from them some fact of practical value. Mr. Beach alluded also to the interest he had always had in whatever Mr. Burton wrote about, and it was the common-sense, useful character of what he said, applicable to the understanding of those looking at photography from a practical standpoint, that undoubtedly made his articles so interesting. He remarked that Mr. Burton was a member of the London Camera Club, so closely affiliated to our New York Society, and on that account he wished him a very hearty welcome, assuring him that he would have the best wishes of the Society in his journey across the continent, and to the final end of his trip to Japan. He was going from a highly civilised to a comparatively uncivilised nation, where he would no doubt exert an influence for good.

A toast of the "Photographic Press" was then responded to by Dr. Elliott and Mr. W. I. Lincoln Adams. Dr. Elliott entertained the same opinion of Mr. Burton's writings as the previous speaker; he wrote in such a way that they always liked to read it, but it was a greater pleasure to see the man and make his acquaintance.

Mr. Adams remarked that he, perhaps, had seen more of Mr. Burton than any of the others, and found in him a very genial gentleman, quite unexpectedly American in his ideas and manner. Having become personally acquainted with the author of so many articles on photographic subjects he should read his future writings with much greater interest. He wished him a pleasant journey, and he knew that all present hoped his undertaking would be successful.

Mr. Burton, in replying, could only give his sincere thanks to all for the very cordial and generous manner in which he had been treated. Everywhere he went he found American photographers very willing to assist him and give information; in this respect he thought they differed somewhat from the English photographer, who, as a rule, was quite jealous of what he knew, and endeavoured to create the impression that his knowledge was superior to any one else's. Because of this feeling he was afraid an American photographer going to England would be coolly received. He was sorry to have to confess it, but believed it would probably be the case in view of his agreeable reception here. He was struck with the small number of societies and clubs in New York. They are so plentiful in London as to enable one to attend a photographic meeting nearly every night in the week. There was in London in a majority of clubs a remarkable assimilation between the amateur and professional photographer, as well as of dealers and manufacturers of photographic materials. All were placed on an equal footing and never stopped to inquire what was the nature of their business or standing. The Camera

Club, in which he was interested, was the largest, and was intended only for amateur photographers. They had a dark room for the use of members, but all the other portions of the premises were devoted to club purposes, having convenient chairs, lounges, &c., where one could have a pleasant chat, smoke, &c. The London and Provincial Photographic Association, he thought, was the most progressive and American in its ideas; they frequently had lively discussions and jolly times. The Parent Society, he said, was quite stiff and formal; a paper was read, a few remarks made, and the meeting adjourned. While professionally he was a sanitary engineer, yet he had a peculiar fondness for photography, and he could only say about himself that he loved to write about it, and was glad to learn his articles were appreciated here. He desired to specially thank the firm who had so kindly interested themselves in his behalf while here, and closed with expressions of goodwill to all present.

It was unanimously resolved that he be proposed as an honorary member of the New York Society at its next meeting.

The entertainment closed at a late hour. It will no doubt form a pleasant remembrance to Mr. Burton when he reaches the sunny climes of Japan. All wished him God-speed and a safe journey.

New York, April 23, 1887.

F. C. BEACH.

COATING PAPER WITH EMULSION.

It stands written in a very valuable hand-book of photography in my possession, that the difficulties connected with emulsion work on paper are so many that the amateur would do well not to attempt it. Ever since reading that sentence I have been longing to prove its falseness, but until lately have never been in a position to do so, owing to want of a room in which to carry on my experiments undisturbed by the powers that rule my modest establishment.

That there are difficulties in the process I freely admit, but I also know from experience that they can be overcome by any careful, cleanly manipulator; and I gladly give my experience for the benefit of all brother amateurs who may care to profit by it, assuring them that if they will follow my directions carefully and intelligently, they will have no difficulty in turning out finished prints of their own make, from beginning to end, which will meet the demands of the most exacting, and at a fraction of the cost of the commercial article.

THE EMULSION.

No. 1.	
Gelatine (soft)	42½ grains.
Bromide of potassium	26 "
Water (distilled).....	1 ounce.
No. 2.	
Nitrate of silver	32½ grains.
Water (distilled).....	1 ounce.

Dissolve the bromide first, then add the gelatine, and dissolve by gentle heat (95° to 100° Fahr.); bring the silver solution to the same temperature, and add in a small stream to the gelatine solution, stirring vigorously, of course, in non-actinic light. Keep the mixed emulsion at a temperature of 105° Fahr. for half an hour or an hour, according to the degree of sensitiveness required, previously adding one drop of nitric acid to every five ounces of emulsion. Allow it to set, squeeze through working canvas and wash for two hours in running water. In my own practice, I manage the washing easily enough by breaking the emulsion up into an earthen jar filled with cold water, and placed in my dark room sink. A tall lamp chimney, standing in the jar immediately under the tap, conducts the fresh water to the bottom of the jar, and keeps the finely divided emulsion in constant motion; a piece of muslin, laid over the top of the jar to prevent any of the emulsion running out, completes this simple, inexpensive, but efficient washing apparatus.

The washing completed, you are ready to melt and filter the emulsion preparatory to coating the paper. When melted, and before filtering, it is well to add of glycerine and alcohol each about one-tenth of the whole bulk of the emulsion, the glycerine preventing troublesome cockling of the paper as it dries, and the alcohol preventing air-bubbles and hastening the drying. This addition made and the emulsion filtered, you are ready to coat your paper, which may be coated just as it comes from the stock dealer, plain Saxe or Rives, or, better still, given a substratum of insoluble gelatine, made as follows:—

Gelatine.....	1½ grains.
Water.....	1 ounce.

Dissolve and filter; then add eleven drops of a 1:50 filtered chrome alum solution. The paper is to be floated for half a minute on this solution, avoiding air-bubbles, and then hung up to dry in a room free from dust. The purpose of this substratum is to secure additional brilliancy in the finished prints by keeping the emulsion isolated from the surface of the paper. If you are floating the whole sheet, now is the proper time to cut it to the size you wish to coat, but for anything less than 6½ x 8½ I would recommend cutting in double or quadruple sizes, 8 x 10 for 5 x 8 and 4 x 5 prints, as the paper is easily cut down after the emulsion is dry.

COATING.

Apparatus.—A stone, marble, or glass slab large enough to hold at least half a dozen glasses of the size paper you are coating, and most accurately

levelled; a dozen or more pieces of glass of the same size as your paper; a porcelain or agateware tray of the same size; a ruby lamp; a deep tray of a size to hold your jug of emulsion and the smaller tray; a spirit or kerosene lamp enclosed in a box suitably ventilated and protected against the egress of white light from the lamp inside (this is easily secured by punching holes around the top and bottom of a tin box of suitable size and covering it with another somewhat larger in every way, but without a top); and a goodly supply of spring clothes pins, to be had of any hardware merchant for twenty cents a dozen. The above is a complete inventory of my own outfit. Having then provided yourself with these articles—with the addition of a squeegee muffled with a piece of soft flannel, an article which you can easily make by procuring a piece of small black rubber tubing of the proper length, and placing it in the centre of a strip of flannel of equal length and about two inches wide; you then fold the flannel over on itself, thus enclosing the rubber tube, and fasten the whole between two narrow, thin strips of wood, drawing the rubber up close to the wood—you are ready for coating. For this purpose, you must secure the temporary use of some small room in which the paper can be coated, hung up, and left to dry. This room must meet three requirements; it must be dry, free from dust, and capable of being made absolutely light-tight during the drying of the paper. I am fortunate enough to have undisputed control of a small attic which serves admirably. Into this room, provided with a table large enough to hold your marble slab, on which the slab is carefully levelled, you carry all the articles mentioned above. The spirit or oil lamp is placed in its box on which stands the large tray previously filled with water at 100° Fahr., and containing the jar of emulsion and the small tray filled with warm distilled water. The ruby lamp stands on a table in front of you, the glasses well cleaned and warmed to blood heat, and the paper, with the side to be coated uppermost, are placed on the table at your right; within convenient reach of your right hand stands the tray of warm water, and the levelled slab is within easy reach on your left. Turn the ruby lamp down as low as is consistent with the power of vision. Now immerse a sheet of the paper in the water in the small tray, leaving it there for a minute or two; then place it accurately on one of the glass plates, and sweep off all superfluous water with the squeegee, at the same time removing all wrinkles and air-bells, and place in an upright position to dry slightly while you prepare a second plate in the same manner. Now balance the first plate on the tips of the fingers and thumb of the left hand, and pour on a sufficient quantity of the emulsion, about one drachm for every ten square inches of paper. I use a silver soup ladle holding just enough to cover a whole plate. Gently tilt plate from you until the further end is completely covered; then, as gently, tilt it towards you until the emulsion completely covers the paper; then carefully place it on the levelled slab to set. Continue this operation until the slab is covered, when the paper first coated will probably have become sufficiently set to be stripped from the glass and hung up by clothes pins to dry, which in my room requires from six to ten hours.

As to the exposure and development of this paper, no special directions are needed. The proper exposure with the light and negatives used will be learned by a few experiments. The developer is the usual oxalate and iron mixture, both solutions being kept slightly acid.

Negative paper is prepared in the same way, substituting a more rapid emulsion for the slow one given above.

It may be worth noting that very good matt surface prints can be made by coating ordinary drawing-paper of light or medium weight with this emulsion, but for contact printing from small negatives the results are rather coarse.

REV. W. H. BURBANK.

—*Photographic Times.*

ARCHITECTURAL PHOTOGRAPHY.

The photographing of architectural subjects in general has been rightly classed among the easier departments of our art. Given a fine building standing in a favourable position for light, and the distance at which the camera must be placed, and it will be a simple matter to treat it photographically. It will be seen, however, that, in speaking thus, we leave ourselves a large loophole to creep out of; for if we take the experience of operators who have worked in other lands, where architecture is a chief feature of the average street view, we will find that the work is often beset with trials and difficulties, and, on second thought, we can recall cases in this country where the subject has presented itself in anything but a favourable manner to the camera.

This leads us to the consideration of the first point in architectural photography—namely, the approach to the building. We believe that the great majority of subjects of this kind are best taken from the street, because the spectator is supposed to look at the building from this position. But to speak practically, it will often be impossible to carry this out, owing to crowds of people and vehicles, or to the fact of there being insufficient space around the building. This cramped-in and short approach to public edifices is even worse for the camera than for the eye of a critical observer, inasmuch as the photographer will be driven to the use of wide-angle lenses, and find his perspective lines sadly forced and unnatural. In cities and towns where the streets run at right angles, and the architectural subjects are built up close to the pavement line, it will often be quite impossible to obtain a view of the whole of even one

of the facades. Sometimes an end, with a side seen in perspective along one of the streets, may be photographed; but the question may well be asked, whether the results will be worth anything. Even for the common purposes of business advertisement, such prints will not be useful, just because the perspective, even if mathematically correct, will be false to the eye, thus making the view hardly recognisable. Any one desirous of photographing the new Post Office in Philadelphia would be met by a difficulty of this kind, while some of the handsome churches on North Broad-street, having more space in front of and around them, would be easily taken.

Whether the building is to be considered as forming a part of a street view or not will depend on the taste of the operator, and the general character of the view. Street views, as a class, will be more interesting if made instantaneously, so as to show the travel, and thus give life and animation to the picture. But when a large plate is to be used for some edifice that will arrest the attention at once, and keep it fixed, we believe that so far from any gain to the picture, there would be positive loss if many figures were introduced; and, again, an instantaneous exposure would be very apt, indeed, to leave patches of crude, black shadow without detail. An exposure long enough to leave no doubled outlines from people, waggons, &c., but only a slight streakiness over those parts of the foreground where the street was seen, would be preferable in almost every case.

Assuming that there is space enough about the building to enable the operator to take any position he pleases, the question now meets us, whether the camera should be placed near or at a distance—a wide-angle lens, of course, being necessary in the former case. If the camera be set far away, and a long-focus lens be used, the picture will have a very natural and realistic appearance, and at times may even be tame, like an architect's plan. A closer position, with a wide-angle lens, while (as we have already hinted) not being so truthful perhaps, might give a more pleasing result. Thus, there will be ample opportunity for the operator to show his good taste.

Full sunlight proceeding sufficiently from one side or the other to throw shadows from the prominent or jutting portions, will almost invariably be the most pleasing. It has been well said that shadow is the "glory of the picture," and it also serves to "explain the lights." It is just this light that can but seldom be had on those portions of a building facing the north; so that if an overcast day be waited for, in order to be able to direct the camera southwards, the details will often be finely rendered, but the picture, as a whole, will be apt to look tame and flat, if compared with those made in sunlight. A partial remedy for this will be to make the negative rather denser than usual, so as to give a vigorous print with strong contrasts. It would be well, before determining upon the work, to see the building soon after sunrise, or just before sunset, particularly in the early summer months, as there will often be a weak, though beautiful, side sunlight on the northern front, for a brief time, early and late in the day.

The outfit for architectural photography will be much the same as for landscape. A swing back will always be required, and if the camera is not square, but has to be reversed on the tripod for upright views, a double swing must be adapted, so that high church spires, &c., may be included without tilting the camera and distorting the perpendiculars. When the swing back is used, care must be given to the focussing; as it will be necessary to raise the lens panel, the centre of the defining power of the lens will, of course, be thrown down towards the foreground, leaving the tops of spires or towers in bad focus. The actual centre of the plate, or even a higher point, should then be chosen to focus upon, and a small stop be inserted to equalise the definition. The lenses used should always be rectilinear, single view lenses being seldom or never suited for this kind of work. The camera, also, should be carefully levelled in both directions, and mounted on a good, steady tripod.

All of our remarks, of course, apply to exteriors only. Interiors will be found to offer difficulties of another kind, which we cannot treat of here.

—*American Journal of Photography.*

ELLERSLIE WALLACE.

BALLOON EXPERIENCES OF A TIMID PHOTOGRAPHER.

As the season is now approaching for the ascent of balloons, and much attention is drawn at the present time to the subject of celestial photography, we have reprinted for the benefit of our readers the following graphic and interesting record of a photographer's "experiences" from our valued contemporary, *The Century*:—

MY FIRST ASCENSION.

Although I had always wished (as who has not?) to taste the pleasures of a balloon ascension, yet, when in July, 1885, Mr. A. E. Moore confided to me that he was having a large balloon built, and asked my opinion concerning the possibility of photographing from it, nothing was further from my thoughts than that I should ever realise my aspirations.

Later Mr. Moore consulted me about the construction of some parts, but still I had no suspicion that I was destined to be his companion in two ascensions.

The first ascension with the new balloon was made from Winsted on July 29; and on his return from what was to him an eventful trip, Mr. Moore proposed that I should go with him, and attempt the feat of

photographing from the balloon. This direct proposal nearly threw me into a fever; but I wished to go, and had a good degree of *theoretical* confidence in the success of the venture. After a serious consideration of the matter, I decided to accept the offer, and after this decision, which I felt to be final, went about with the emotions of a criminal whose sentence is deferred; for the day of the ascension had not been fixed. As, however, we expected to ascend soon, it became necessary to make all the photographic preparations at once; and I wrote my orders for apparatus and materials in such a condition of nervous apprehension that, to this day, I wonder that they were understood.

At length Mr. Moore came to me "with a piece of bad news," as he put it. There was to be an ascension on the 2nd of September! Upon receiving the announcement, my heart stopped for two beats, and then went on to make up for lost time.

Feeling now that I had but a week to live, my preparations and experiments were continued with great care. If a balloon was mentioned in my presence, my heart would give a fearful throb, and I could feel myself grow pale; if I glanced up at a cloud floating high overhead, the thought would instantly come, "Perhaps I may go higher than that cloud!" and I would at once grow sick and faint with the dizzying fear.

I detail the "premonitory symptoms" with such minuteness, in order to show that no one who ever thinks of making an ascension can possibly dread the experience more than I did, and to give the reader some faint idea of the revulsion of feeling which took place when the ascension was made, and I at last found myself where I had feared to be—higher than the clouds!

On awaking in the morning of September 2, I was somewhat comforted to find that a strong wind was blowing from the north-west; but on visiting the ground from which the ascension was to take place, I was shocked to discover that preparations for the inflation were already begun. I heard a gentleman say to the aeronaut, "Isn't it too windy for you to go?" and listened eagerly for his answer, which was a confirmation of my worst fears: "Oh, no; we wouldn't go if there was not wind enough to take us away from Winsted."

After partly inflating the balloon, it was decided, notwithstanding this courageous declaration, to wait awhile, and let the wind moderate if it would. At noon the wind was still strong, and to my great relief it was thought best to wait until two p.m. Two o'clock arriving found the wind apparently as fresh as ever, and after a consultation another postponement was made to four o'clock. Then, if the wind continued as strong as ever, Professor Brooks was to go alone.

During the day some of my kind friends advised me not to go; others offered to bet that I wouldn't; and some one started a story that I had backed out. These latter persons receive a large share of gratitude, as they helped materially to strengthen my resolution.

A large part of my fear was lest when once up, and too far away for retreat, my fears might serve to unfit me for the business for which alone I was to be taken from the earth.

As four o'clock approached, the inflation was resumed, and I noticed with an increase of alarm that the violence of the wind was much abated; but, after all, there was a chance that only one could go up, as the gas, which had been standing in the balloon since morning, had lost much of its buoyancy.

At last the great balloon was filled, and rounded out to its enormous proportions above the heads of the crowd. It is necessary for the passengers to take their places before the basket is attached to the netting. Moore took his place, and I was told to get my apparatus and get in; camera and plate boxes were brought from their place of storage, and I made my way back through the crowd gathered around the balloon, conscious of being very white, and moving very carefully to avoid trembling.

Even to the last moment the vague hope, which was half a fear, remained that the buoyancy of the gas might not be sufficient to carry both the aeronaut and myself. The car contained, besides its two passengers and a rather bulky amount of photographic apparatus, a large coil of rope attached to the anchor, and two bags of sand for ballast, with a frame intended to hold my camera perpendicularly over an opening which had been left in the bottom of the car for the purpose of taking views directly beneath us, and a bag containing three pigeons. Having taken our places in the car, the hoop was raised above our heads, and the cords from the balloon netting were connected with pegs attached to the hoop, which in its turn is permanently fastened to the car by cords. Those who were holding the cords from the balloon were directed to let it up, while a few men took hold of the car, to test the lifting power of the machine. In this final moment of uncertainty my breath came short, and it was hard to resist a wild impulse to separate the cords, which seemed to me like prison bars, and make my escape through the crowd.

It was quickly ascertained that the balloon had sufficient lifting power, the word was given to let go, and with a gasp I caught one deep breath, as though in preparation for a plunge into water, as with a dizzying whirl the car swung to its position under the great gas bag, and we were off!

I had looked forward with indescribable fears to the time when I should feel myself torn from the earth and lifted rapidly into the sky; but now that the time was come, how unlike was the reality to my anticipations! Instead of seeming to be carried rapidly upward, we felt as though standing at ease upon a secure support, while the crowd from the midst of which we had just started sank quickly below us, and was soon out of sight and hearing. Many things combine to make this my first ascension

more impressive and more vividly remembered than any other, though they should be counted by the hundred. On the occasion of my first ascension my emotions before starting formed a strong contrast with the experiences directly following, which did not occur in so great a degree again, as before my second ascension the distressing fears previously experienced were almost wholly absent. To complete the inflation of the balloon, and attend to the smaller details in the arrangement of the various apparatus, all of which are important when we consider that our lives are to hang literally by a thread, consume much time; so that our ascension was not begun before five p.m., when the sun had set behind the hills and the chill of gathering darkness was felt.

We were soon lifted from the gloom of deepening twilight into the full glow of light and warmth from the sun, which, as we were carried up, presented the singular effect of a sudden sunrise in the west. This change in our physical condition was paralleled, in my own case at least, by an equal change in my feelings; as we rose from darkness to light my spirits rose from a sickening fear to a wonderful sense of relief from danger. At last, turning my attention from the town we had left, and looking around I was amazed at the wonderful widening of the horizon. From the point of our departure the view was shut in on all sides by the near hills; at the next glance the Highlands and Catskills of the Hudson were in sight, while the view to the east was without limit, the eye ranging at will over stretches of hill and valley, as one might look out over the ocean.

Any person who makes a balloon ascension is sure to hear from his friends one question, many times repeated, "How did it feel?" After an earnest attempt to answer this question, I have been driven to the conclusion that the sensations of an ascension take the form of a tremendous mental impression, instead of producing any noticeable physical manifestations. In my own experience the paralyzing fear felt at starting was entirely lost before we had risen one hundred feet, being followed by the emotions of surprise and wonder, growing into a strong feeling of awe and joy, which continued through the whole time we remained in the air. All fear and dread were lost so suddenly that before we had been ten minutes from the earth I found myself wondering at the change, and trying to recall my former feelings for comparison with those of the present. As the balloon rises gradually, the many sounds of earth, striking the ear at first with confusing variety and force, grow quickly faint and distant. Soon only the loudest sound reaches us, and at last we attain an altitude which no earthly sound can reach. The only physical sensations noticed by me at any time are the ringing in the ears caused by the unbalanced pressure behind the tympanum, which may be relieved by swallowing, only to return again as the balloon is rising or falling; and, at the greater heights, a curious feeling of lightness and inclination to breathe fuller and more frequently in the rarefied air.

After our departure from the earth, and my recovery from the first impression of surprise, the rustling of the doves, our unwilling companions, attracted our attention. One of them was quickly set free, and, after circling about the car a few times, decided on the proper course, and soon disappeared in the direction of Winsted. It was at about this time that our attention was attracted to the peculiar appearance of Long Lake near Winsted. From the altitude at which we were sailing, the whole surface of the lake was in sight far below, giving us an excellent idea of the comparative size of its three bays and of the outline of its very irregular shores. The rays from the sun, still high in the west, were reflected directly to us from the surface of Third Bay, causing so bright a spot upon the rippling water that it could only be glanced at for an instant; nor was the camera's eye less dazzled than ours, for a spot of white appears upon the picture of this scene, a photographic record of the phenomenon. The race track east of the lake, so far below that the buildings were hardly visible, was apparently of about the circumference of a one-cent piece, and perfectly elliptical in shape.

Another dove was now thrown out, its actions giving us sufficient proof, were all other means lacking, of the increasing rarity of the air, as it exhibited much hesitation at leaving us. At first its wings beat the air rapidly for a short flight; then it returned to the balloon, perching upon the hoop near our heads; seeming at last to gather courage for its plunge, it spread its wings, and, describing a series of ever-widening circles, was soon out of sight far beneath us. Now as never before could I realize the great variety of lake scenery in Litchfield county. One hundred bodies of water are indicated upon a map of this county, and it seemed to us that a large proportion of them were in sight at once, either sparkling brightly, as they reflected the setting sun, or lying, dark and cool, in the shadow of the hills.

While passing directly over Shepherd's Pond, in New Hartford, Mr. Moore referred to the statements made by former aeronauts as to the ease with which the bottom of lakes and rivers might be seen; it was apparent to us that such statements should be made with caution, or some explanation should accompany them. There would seem to be only one position from which, under the proper conditions, it is possible to see objects at a considerable depth under water: the observer must be at not too great an angle with the vertical, and the water must be quite smooth. It is also necessary that the sun should be low down, so that there shall be no direct reflection of light from the surface of the water; and though in the case of a shallow pond the whole of the bottom might be seen, yet, when the body of water is of much depth, the bottom is only visible near the shore, except when the water is quite clear and the

bottom has a light hue, reflecting the light which has reached it through the water.

Having at length gained an altitude of over six thousand feet, it was decided to part with our last dove, which was accordingly dropped from the bag in which it had been confined. The singular actions and evident fear of the creature excited at once our interest and pity. Three times, after as many attempted flights, the dove returned to perch on the hoop attached to the car, breathing rapidly, and evidently exhausted by the violence of its efforts to sustain itself in the rarefied air. At last, as we persisted in driving it away, it made another attempt at flight, which proving ineffectual, it was seen to turn and plunge directly downward with a velocity which soon carried it beyond our sight.

As we continue rising, the scene becomes every moment more impressive in its grandeur; the earth, with its network of streams and roads spread out below us, resembles a marvellously perfect map, with every variety of colour and shading. The silence is absolute, unless broken by our own actions; and the experience of being carried along without effort or consciousness of motion, over this wonderful picture, can never be forgotten. While sailing through this desert of silence, the least sound proceeding from the balloon or its occupants is startling in effect; the blood is plainly heard as it pulses through the brain; while in moments of extra excitement the beating of the heart sounds so loud as almost to constitute an interruption to our thoughts. The sound caused by a slight shifting of the gas bag inside the netting occasions frequent starts of alarm; and the cracking of the willows of which the car is woven causes an involuntary grasp at the hoop or ropes. The sensation produced by a little gust of wind, often felt upon the face while the balloon is passing from one air current to another, is weird and unearthly, and has caused me to glance in the direction from which it came, with the idea that I felt the breath of some invisible being.

At last our barometer indicated an altitude of 7200 feet, after which we began to descend slowly. From this height we enjoyed a magnificently extended view over an area much larger than the State of Connecticut. To the north, Mount Tom and other mountains of Massachusetts were in sight, as small points above the dead level of the horizon; to the east, beyond the Connecticut river, no prominent objects arrested the attention, but the landscape gradually rose up to the horizon, at the level, apparently, of the eye, showing many miles of country beyond the river; to the south lay Long Island, beyond the narrow line of light which we knew to be the Sound; while in the west, after ranging over the hills and valleys of Litchfield county, the eye rested upon the Catskills and the mountains forming the Highlands of the Hudson.

The map-like effect of the landscape is very striking. The course of streams, with the different railroads and highways, may be traced for many miles, dividing the country into irregular plots, which are again subdivided by the farms. I was pleased to see the large area of forest which still remains, notwithstanding the great amount cut for lumber and the land annually cleared by the iron manufacturers.

As our highest point had been reached, after which the balloon began to descend, we were compelled to resort to our ballast in order to remain longer at a considerable altitude. The frame mentioned as having been intended to hold my camera was first thrown out, as it was found to be unnecessary in our work; we watched it as it fell, whirling round and round until nearly out of sight.

The sunset scene was one of the most beautiful I have ever witnessed. From clear, dark blue overhead, the sky gradually shaded down into deep red in the west; and in this glorious setting of colour the sun, seeming slightly flattened, as when seen sinking at sea, blazed out a deep orange colour.

Suddenly our attention was caught by the blowing of a number of whistles; we were again within hearing distance of the earth. My first thought was, "We are getting a salute;" but we soon found that the whistling was from the factories in the many towns below us. In our position the sound of whistles from many places could reach us at once, as all were blown at the time for stopping work. At this time the trains on several railroads were in sight, and we could hear their rumbling faintly, while a surprisingly long time elapsed between our sight of a puff of steam from a locomotive and the hearing of the whistle. The balloon continued to descend, and soon we could distinguish human voices; some remarks were exchanged with the inhabitants of the farm-houses we were passing.

An interesting phenomenon observed by us, and to which I have seen no reference by other aeronauts, is the distinctness of the echo returned from the earth. When within easy shouting distance quite long sentences are returned with startling clearness; many times I was deceived into thinking that those below were mocking us by a repetition of our questions.

The order to pack the instruments caused me a feeling of deep regret that my voyage should end so quickly. Having left the ground with the greatest reluctance, I was about equally unwilling to return to it. As the balloon descended, we were rapidly nearing a hill, the western side of which was a precipice two or three hundred feet high, while its flat top was thickly wooded. Well knowing the inconvenience of a landing in the woods, Mr. Moore at once threw out the last of our ballast in the hope of clearing the trees; but the balloon sunk rapidly, and soon we could hear the rustling of the wind through the tree tops, and then the chirping of crickets. One or two sand bags were sacrificed, and Mr.

Moore was stooping to remove his shoes, when I saw that we should clear the woods, and we turned to see where the balloon would land. Not until then did we see that the land beyond the trees was on a lower level; in fact, that the east face of the hill was higher and more abrupt than the west. Our balloon cleared the trees by only a few feet, and we were then directly over the precipice. All consciousness of support from the balloon was for a moment lost; we seemed to be falling, and I was aware of gasping for breath as we sank over the edge. This impression was of short duration, yet I learned in that moment how it feels to fall from a great height.

Our confidence restored, we glanced back at the grey, lichen-covered rocks, and then down to the pasture towards which we were gently sinking; we narrowly escaped the top of a large tree, and descended to the ground so slowly that we might have gathered leaves from the tree in passing. We struck the ground so lightly that I hardly felt the shock, and then, standing in the car while the gas was escaping, I could feel the relaxation following a period of intense excitement. Soon the sound of hurrying feet was heard, and quickly a party gathered about us, all eager to help and ask questions. JOHN G. DOUGHTY.

(To be continued.)

EXPRESSION IN PORTRAITS.

STOTHARD said, "There is nothing more difficult than to paint people doing nothing." This is the daily, hourly task of the photographer, and yet he rarely seems impressed with the importance of the undertaking. In a brief forenoon, he will give you a dozen or twenty very glaring counterfeit presentments of the human face divine, and without the slightest compunction of conscience, nay, with a profound feeling of the sublimity of the occasion, write beneath his card, in beautiful scroll, "Artistic Photographer."

Did you ever stop to think that it is not sharpness or brilliancy or excellence of finish, or even softness of lighting and beauty of pose, which entitle you to this assumed title. You may have all these qualities in your work, and yet, if you have not expression, they profit you nothing for entering the kingdom of art. How shall we attain to it? you ask. Our subjects are unpoetic, lack individuality, lack expression. How shall we call forth this quality from commonplace people? We answer, this Stothard, whom we have mentioned, had the same sort of people to deal with, or he would not have given utterance to the words he did. All his work is direct from nature, not idealised. Hogarth had even more difficult subjects to deal with than you have. In Stothard's picture of the procession of "Charity Girls," he was obliged, according to the terms of the contract, to make portraits of the foremost figures, therefore to show their faces and their individuality; yet he has overcome the difficulty with wonderful skill, and the work is really one of the most original and interesting pictures he ever painted.

One sometimes fears that the principles applicable to painting are a little too high for the range of photography. Maybe they are sometimes, but the attempt to reach the high mark is healthful exercise, and the results, though they fall short, will, nevertheless, be better than if we aim not at all.

But it is not our intention to worry you with any rules of art, or to ask you to apply them to secure beauty of expression, because we do not think all the art rules in the world will give you the faculty. We desire only to call your attention to a feature in the human face, which is, as the Bible puts it, a very "unruly member." Need we say—the mouth. Beware how you try to control it. Leave it rather to its own sweet will. Every photographer has his own way of managing his sitter, but his way is generally to make the subjects as uncomfortable as possible. They have come to know this, and are generally so accommodating that they try to get in the uneasy frame of mind the minute they enter his studio. Their mouths becoming the silent utterers of their state of mind.

Of what help are the reassuring words, spoken with solemn accent: "Assume an agreeable expression"—"Try to look pleasant." This pleasant aspect becomes but a sort of mongrel smile. Most men are fortunate in the possession of a beard and moustache, which hide the photographically acquired, or congenitally inherited, defects, therefore their portraits are generally more agreeable in expression than the portraits of women. The mouth plays the most essential part in the expression. The eyes which seem to smile or look sad, in reality do nothing of the kind. The mouth is the key to interpret their feeling. The muscles which move the lips tell whether the eyes are joyous or sorrowful.

We all have seen those drawings in Bell's *Anatomy* which are so arranged that the lower half of the face can be covered with a slip, in which the mouth is a sad or laughing one, while the upper part remains the same. By this simple device we may transform a sad and saintly Madonna into a smiling nymph, in which the eyes twinkle with roguish delight. This beautiful play of the muscles of the mouth is so delicate that it at once responds to the sympathetic action of the mental condition, betrays the disposition, and so mirrors, if uncontrolled either by the will or other exciting cause, the true character of the person. Hence, the action, if natural, is involuntary, and any endeavour to govern it by the will shows at once upon the face, and we have that look of determination—that "screwing up to the sticking point" expression—which is generally

called the photographic look. Expression centres in the mouth. It is the feature for the photographer to exercise his skill upon. We are not going to give any instructions how to conquer it, because we do not know how. The action of the photographer's will would be as bad as the operation of the owner's.

The only thing which seems proper to do is to take away restraint of any kind, to relieve the model from the impression that he is the chief factor in the transaction. If some photographer would have the sense to consign his position chairs and his inquisitorial head-rest to the lumber room, there to feed oblivion with their decay, and make his operating room, not his reception room, look something like an artist's studio, it is possible the expression of his models might improve. We have seen very happy expressions in photographs, and on inquiring, found that they were taken without head-rests and without ceremony. The models were left to their own free-will, or rather they were not told when the operation began or ended.

Our plates are so very sensitive that we need no longer summon the attention of the sitter, or announce, with majestic mien, "The exposure is now about to begin." If a head is properly illuminated, less time will be required with a moderate light than when unevenly lit in a strong light, because a violent lighting gives the high lights the allopathic dose and the shadows the homœopathic.

Finally, expression is very difficult to secure; but so is everything else which is worth anything. With all thy gettings, get expression.

—*American Journal of Photography.*

JOHN BARTLETT.

MAKING ORDINARY PLATES ORTHOCHROMATIC BY BATHING WITH ERYTHROSINE.

WHEN orthochromatic methods first commanded the serious attention of practical photographers by the admirable and surprising results which were produced, there were two methods of preparation then in vogue: sensitising the emulsion for colour values by mixing with it a certain dye previous to coating the plate, and bathing the already coated emulsion plate with a colour-sensitive solution.

For the reason we have given, the latter method is the only one which has been very widely adopted in this country, and it continues to grow in favour and practical application in America, as well as abroad, while the former method is but little used.

Repeated and prolonged experiments with the various colour sensitisers have resulted in proving to our satisfaction that for the practical photographer, be he professional or amateur, erythrosine is the most effective, while it is the simplest of application. It is, moreover, so sensitive to yellow rays that with it photographing by artificial light, as gas or petroleum, becomes an easy matter.

Any photographer may make his own orthochromatic plates, and any good plate may be successfully rendered orthochromatic, by simply bathing it with the erythrosine solution. When orthochromatic plates are used for reproductions or landscape work, it is advisable to colour sensitise plates of only moderate rapidity. The formulæ are as follows:—

PRELIMINARY BATH.

Aqua ammonia	1 drachm.
Water	7 ounces.

COLOUR BATH.

Erythrosine.....	1½ drachms.
Aqua ammonia	2 "
Water (distilled).....	5½ ounces.

And the directions are simple.

Immerse a plate of medium sensitiveness in the preliminary bath and allow it to remain therein for three minutes. After removal, drain well, and, without washing, plunge the plate in the colouring bath, rocking it gently to secure uniform contact with the solution. The plate should not remain in the colour bath longer than seventy-five seconds, as a long continued exposure to the colour solution will depress the general sensitiveness, without increasing that for colours. If a large number of plates are prepared with the same solution, it is advisable to add, after the eighth or tenth plate, about ten or twenty drops of erythrosine. The coloured plates must be well drained, reared upon blotting-paper, and dried in the ordinary drying closet.

Coloured plates may be exposed while still wet, and the general sensitiveness is somewhat increased thereby. If, however, the object to be photographed requires a very long exposure, it is better to use a dried plate.

Developing erythrosine plates offers no serious difficulties, but it must be remembered that the plates being so sensitive to colour, especially yellow, the process must be carried on either in the shadow of a subdued ruby lantern, or a light obscured by several thicknesses of brown tissue-paper.

With the interposition of the yellow screen, which is absolutely necessary for the copying of objects in which blue and violet predominates, the time of exposure must be increased from three to six times that of an ordinary plate.

For portraiture, a more sensitive plate may be employed, but the

amount of ammonia in both baths must be reduced fifty per cent. Unless there is an abundance of blue or violet drapery the yellow screen may be dispensed with in making portraits.

Department for Inexperienced Photographers.

THE FOCUS OF LENSES: BACK FOCUS—EQUIVALENT FOCUS—CONJUGATE FOCUS.

THE above terms are not only puzzling to inexperienced photographers, but are sometimes troublesome to those who have practised the art sufficiently long to be enabled to take good pictures.

Broadly speaking, the focus of a lens is that place at which rays transmitted through it are made to converge to a point. But this explanation does not cover all the ground.

The term *back focus* is an entirely misleading and unscientific one, and is useful for only one purpose, namely, to afford camera makers an idea as to what lens will suit a certain extension of camera; but as applied to any of the combinations in use it is absolutely meaningless as regards their focus. It is merely a mechanical term signifying that when any object is in focus on the ground-glass of the camera, this glass screen will be so many inches from the inner end of the lens mount. In one instance only does the back focus convey a correct idea of the real focus. This is when the objective is a single landscape one of plano-convex form, and in such a case the focus is the distance between the back or convex surface and the ground-glass.

It would serve a much more useful purpose if opticians, instead of speaking of their lenses having such or such a *back focus* (which, as we have stated, means nothing), would give the distance between the face of the flange and the ground-glass, and speak of it as the "*flange focus*." This, although optically absurd, would at least possess the merit of affording a ready means whether any lens in particular would be adapted for use with any definite camera.

Equivalent focus implies a certain something to which it is equivalent. It is so termed from an image formed by it equalling in dimensions that made by a single lens, such as a spectacle glass. Now, let an image be formed on the ground-glass by means of such a glass, and the size of the image—which may be a house, or a portion of a house, or even a couple of trees situated apart from each other—is a factor in ascertaining the focus of any combination of lenses. No matter if the *back focus* of the combination be, say, five inches, and the distance between the ground-glass and the simple lens, which gives an image on the ground-glass the same size as the other, be six or seven inches, the equivalent focus of the combination is precisely that, nothing more or less, of the simple spectacle glass which gives an image the same size as that obtained by the compound lens.

In most lenses of the so-called rapid class the "*equivalent*" focus is the distance (approximately) between the place where the stops are inserted and the ground-glass, and this place is (approximately) the optical centre of the combination. An intelligent reader will, from the foregoing, deduce the meaning of the word "*equivalent*," and will know that it simply means the focus of a single lens, which forms an image the same size as one of a compound nature.

Having explained so much, we now come to the question of ascertaining by other means the equivalent focus of any combination. Seeing that this series of articles is intended for the inexperienced photographer, we desire to make it as simple as possible, and shall avoid describing complex methods.

Place the camera in a window, and point it to a well-lighted scene at a distance. Focus the object, and note that there is a tree, a chimney, or a church spire at one side, the right of the ground-glass, and an equally well-marked object on the opposite side, the left. With a pair of compasses measure the distance apart of such objects, or with a pencil mark their position on the ground-glass. Now remove the lenses from the tube by unscrewing them, and insert a very small stop: a bit of card with a hole punctured in it by a thick pin will suffice. It matters not at what part of the lens mount this punctured card is inserted; indeed, it will serve the purpose equally well if the lens mount is removed altogether, and the card is placed over the flange in the camera front. Now, with a large focussing cloth thrown over the camera and the head, slide the ground-glass in or out until the feeble image formed by the pinhole corresponds in dimensions with the markings on the ground-glass previously made when the lens was in its place. Measure carefully the distance between the card and the ground-glass, and such distance is the

equivalent focus of the lens that was employed in making this experiment.

There are other and rather more complex methods by which the equivalent focus may be ascertained, but, as they have been described only lately in these pages, we refer the reader to our issue of February 11, 1887, page 84, where that will be found given with a reasonable degree of fulness.

The subject of conjugate focus will be treated of in our next.

AN IMPROVED ADJUSTABLE PHOTOGRAPHIC CAMERA STAND.

No. 6936. JOHN BROWN, Elenderry House, Shaws Bridge, Belfast.—*May 24, 1886.*

A SPHERE of wood or other suitable material fixed to the bottom of the camera has fitted on it three cupped or hollowed metal pieces, held against it with moderate pressure by springs, rubber bands, or both combined. Each cup has two pins pointing inwards on which the camera legs fit in the usual way, one side of the divided upper part of each leg fitting on the pin of one cup, and the other side of the leg on that of the neighbouring cup. In two of the legs the divided upper parts are held together by catches or hooks, so as to keep the cups on which they fit from separating beyond a certain distance, or this office may be performed by the springs above mentioned.

The divided upper part of the third leg has a hook with tightening screw, or else an eccentrically slotted hook or other contrivance, for the purpose of drawing the two parts and the cups on which they fit together, and thus binding the whole rigidly together and fixing the camera firmly in whatever direction it has been pointed.

The claim is: The combination of the spherical ball, with a projecting piece or pieces for the purpose of attaching the camera or other apparatus, and the sectional cups or sockets, attachable to the legs and capable of being contracted to clasp the ball as shown and described.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, April 28, at a meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. A. Haddon presided.

Mr. J. B. B. Wellington exhibited three sensitometer tablets, one belonging to himself and two to Mr. Cowan; when all three were excited by the magnesium light they gave visibly different amounts of phosphorescence, and gave different indications upon gelatin-bromide plates.

Mr. A. L. HENDERSON exhibited an advertised device for fixing a focussing cloth in windy weather; it was a bit of wire bent so as to have a hook at each end; he said that a protected shawl pin, as used by ladies, was better for the purpose and one-twelfth the price. He then produced a letter from Mr. J. D. Williams, of Holywell, saying that he was not yet ready to exhibit his new dark slide to the Association.

Mr. H. M. HASTINGS said that he had exposed platinum paper for one minute to daylight to fog it before printing, and that on developing with carbonate of potash solution cold, to which a mere trace of hypochlorite of potash had been added, it developed a clean picture; other portions of the same print otherwise developed were thoroughly fogged. Another piece of platinum paper exposed in the open air near damp blotting paper for twenty-four hours was likewise developed in the same way without fog. The amount of hypochlorite added was in proportion to the depth of the printing; in the case of fogged paper the printing had to be very deep. He thought that this information might be useful to those who had old platinotype paper which they believed to be fit only to throw away.

Mr. F. W. Cox remarked that had an ordinary short exposure been given in all probability the use of hypochlorite would merely have bleached the paper.

Mr. F. M. EDWARDS exhibited several albumenised prints spoilt by spots of different descriptions and asked the causes of the said spots.

The CHAIRMAN thought that the spots on one of the prints might have been caused by particles of soot settling thereupon, and soot being usually charged with a little sulphuric acid, sulphate of silver spots might have been formed upon the picture. When the spots on that print were examined under high magnifying power they seemed to have been produced by something which had fallen upon the paper.

Mr. HENDERSON, after operating upon the same spots with a penknife, expressed the opinion that they were due to metallic dust which had fallen upon the albumenised paper before the albumen had been dried.

Mr. HENRICH THINKS knew of a Continental photographer who had to copy an old engraving spotted by being worm-eaten; he covered its back with thin tissue-paper, filled up the holes with a liquid mixture of paper pulp and gelatine, and when the latter was dry continued the lines of the engraving over the spots by means of a pen charged with Indian ink.

Mr. L. Medland exhibited prints from negatives taken with drop-shutter exposures.

A question in the box asked how many brands of orthochromatic plates were in the market and what was their relative colour sensitiveness.

Mr. WELLINGTON replied that Edwards's and Obernetter's plates were in the market, and that neither of them were sensitive to the red rays. Plates dipped in cyanine blue were sensitive to the red and worked splendidly. He had found something else which worked nearly as well, but which he would not name.

Mr. EDWARDS remarked that if any one wanted to get rid of halation in photographing interiors, he could recommend plates of ground or opal glass coated with emulsion instead of coated plain glass.

Mr. WELLINGTON had found orthochromatic plates to give little halation.

A question in the box asked if common white starch were practically as good as arrowroot as a substratum in paper printing processes.

The CHAIRMAN stated that common starch contained many impurities.

Mr. W. M. ASHMAN said that under the microscope the grains of Bermuda arrowroot were seen to be of tolerably even size, and he had found it to work better than common starch as a substratum.

Mr. HENDERSON would like to know if any objection existed to using as a substratum paraffine wax in such weak solution in benzole that it would not make the paper quite non-absorbent of aqueous liquids. Some such plan might be useful in making stripping films.

The meeting then resolved itself into a committee for the business purposes of the Association.

CAMERA CLUB.

At the meeting of this Club on Thursday last week, Mr. J. Traill Taylor in the chair, Mr. LYONEL CLARK, who had been to Venezuela on business, and had taken with him a camera, gave an exceedingly interesting lecture on his journeyings. He illustrated the same by a large collection of lantern transparencies which he had made from the negatives obtained on that occasion, which included some taken at certain places he had called at in the West Indian Islands.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society was held on Tuesday, the 3rd instant, at the Masonic Hall,—Mr. G. W. Atkins in the chair.

Owing to an informality, the minutes could not be confirmed. The excursion to York for the following day was postponed on account of the unsettled state of the weather. Mr. Joseph Hagne was elected a member.

The CHAIRMAN then rose to put the following resolution:—"That this meeting of the Sheffield Photographic Society desires to express its sincere sympathy with the President and Hon. Treasurer upon the loss which they and their families have sustained by the death of their father, the late Mr. John Yeomans, Town Clerk of Sheffield, which position he had filled for the long period of twenty-nine years, with credit to himself and to the advantage of the borough generally."

Mr. PLATTS seconded the above in a few well-chosen words, and it was carried unanimously.

The question box was found to contain the following: "What is the best artificial light to use in making photo-micrographs by the wet process?" In answer it was stated that good work had been done with a paraffine lamp with some objects, it being merely a question of exposure, which varied with each object; indeed, some were not capable of giving a satisfactory impression upon the wet plate on account of their non-actinic colour. The magnesium light was considered available if kept strictly in the focus of the condenser.

A discussion upon detective cameras ensued, during which Mr. Barber explained the construction of two much in use in the United States. As to the lens most applicable, one of the "rapid" class was recommended where the light was good, but in such a town as Sheffield one of the small stereoscopic portrait lenses would be better, stopped down as found necessary.

Mr. BROMLEY explained the working of the due-ratio drop shutter, which was favourably commented upon.

The meeting then adjourned.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Thursday, the 28th ultimo, at the Royal Institution,—The President, Mr. George H. Rutter, in the chair.

The minutes of the last meeting were read and confirmed.

The following gentlemen were unanimously elected members of the Association:—Messrs. Richard P. Preston, Thomas Comber, J.P., William A. Caldwell and Edward Swinden.

The SECRETARY called attention to the presentation prints for last year, which were on the table, and announced that they would be distributed at Mr. Beer's office to all members applying for them who have duly paid their last year's subscription.

Mr. J. A. FORREST called attention to the serious alteration in colour of the great public buildings in our large manufacturing towns and the increasing difficulty of photographing them, giving instances of public buildings which are now impossible to photograph. He exhibited some paper negatives reproduced from old prints in his possession, from which negatives he could readily multiply prints; also some beautiful prints of the Manchester Town Hall, both interior and exterior, by Mr. Pollitt, of the Manchester Photographic Society, and advised amateur photographers to secure photographs of all such buildings whilst it was still possible.

Mr. JOHN HARGREAVES, F.R.H.S., gave a very interesting description of the objects of antiquarian and photographic interest in the Hundred of Wirral—the peninsula between the Mersey and the Dee—instance Birkenhead, Bidston, New Brighton, Wallasea; Leasowe Castle, containing an old mantelpiece which was originally in the Star Chamber; Irly Old Hall, a black and white building, which he pronounced to be the most picturesque building in the Hundred; Thurstaston; Bebington, with its church, one of the most interesting ecclesiastical buildings in the district; Hooton and Poole Halls; Stanton Abbey, of which there are a few remains, but which the monks left and migrated to Whalley Abbey; and many other places of historic and artistic interest. He mentioned, in conclusion, that his paper would shortly be published in an accessible form, and might serve as a guide to those visiting the Hundred of Wirral.

A cordial vote of thanks was passed to Mr. Hargreaves for his interesting paper, and his kindness in visiting the Association to communicate information.

Mr. J. E. THORNTON exhibited his shutter, which was not ready to show at his previous visit. The shutter is similar to the well-known "Kershaw," but has an attachment by which it opens upon pressure of the pneumatic ball, and remains open as long as the pressure continues, thus providing for "time" as well as "instantaneous" exposures.

Mr. B. L. SAYCE exhibited specimens of fine dry-plate processes from 1861 to 1865, namely, 1, Bromo-iodised collodion with gelatine preservative; 2, The Fothergill process with albumen preservative; 3, The tannin and honey process; 4, Bromised collodion, sensitised in a sixty-grain nitrate bath, and coated with a solution of tannin, gallic acid, and grape sugar (by this the sensitiveness of wet collodion was obtainable in 1863 on dry plates); 5, Examples of negatives and their prints by the collodio-bromide or first practical emulsion process for negatives, introduced in September 1864. Mr. Sayce also called attention to the comparative indestructibility of negatives by the old favourite process, the collodio-albumen, and showed a print recently made from an unvarnished negative twenty-six years old, which had been stored for fifteen years in a damp outhouse, quite unprotected from the moist exhalations of its surroundings.

Mr. J. H. DAY, the leader of the first excursion of the Association this year, on Easter Monday, to Gawsorth and Marton, read a full report of the trip, abstract of which is as follows:—The first excursion of the Association took place, so far as weather was concerned, under most brilliant auspices, for a more deliciously bright, genial, sunny Easter Bank Holiday could not have been desired than was experienced by the little party of eight who started for the comparatively unknown and out-of-the-world region round about Macclesfield, with the object of opening the photographic ball of this stirring Jubilee year, 1887. The party travelled *via* Cheshire lines to Manchester, thence to London Road, and by train to Macclesfield, where a wagonette took them first to Pail Farm, thence to Siddington Church, then to Marton for the Chapel and Marton Hall, where several good pictures were obtained; thence to the old hall of the Fyttons, then back to Macclesfield. The day was a very successful one, no fewer than sixty-four plates or films being exposed.

Mr. PAUL LANGE read a brief report of the second excursion to Hooton and Toole Walls, from an analysis of which it appeared that nine members took part, that the lenses employed were two by Ross, three by Wray, one each by Swift, Newton, and Steinheil, and that forty-seven exposures were made, of which thirty-nine were on glass and eight on Eastman paper, thirty-one of the glass plates used being Ilford and eight Derwent.

Views obtained during these excursions were exhibited by Messrs. Day, Sayce, Lange, Beer, and Riley.

The proceedings closed with votes of thanks to the readers of the papers.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

THE members of the above Society on the 27th ultimo were indebted to Mr. D. Josti for an instructive and interesting lecture on *Retouching*.

The lecturer, who was introduced by the President, said:—Retouching, like other subjects, has an history, although the record does not extend very far back, and in its career has had to contend with varied opinions as to its utility from an art point of view; it has, however, held its place and become an important branch of photography. As a matter of fact, trading photographers cannot get along without it. Scientific photographers were its most determined enemies, and strongly objected to the original work of the camera being tampered with; there were many reasons *pro* and *con*, and I have frequently received strong censure for defending this help to artistic photography. The strongest argument against retouching is that the human eye cannot reach what the eye of the camera can, and that our hand is unable to help the precision of the lens. We must give in to this to a certain extent, but I maintain retouching is a valuable auxiliary. When retouching first took root there sprang into existence a multitude of individuals of very little artistic knowledge, but who embraced a clean and easy method of obtaining a living, and thus heavily handicapped the scientific retoucher. To aid me in making my lecture as complete as possible I endeavoured to consult some works on the subject, but not finding anything satisfactory I must rely upon my own practical experience. In the year 1852 my brother and I possessed a little studio in the Rhetic Alps, and astonished the mountaineers with Daguerreotype portraits. We received intelligence of the new and incomprehensible invention of

taking a negative. My brother immediately departed for Germany, secured the secret, returned, and catered for the new style of portrait. We were delighted with the process but somewhat disheartened on the appearance of several transparent spots, which of course spoilt our prints. Here comes my first experience of retouching; the spots were made opaque by ink and then printed fairly well. Winter came, trade was bad, I therefore migrated to Italy and joined the firm of Messrs. Bianconi, Milan, where I was struck with the splendid quality of the work turned out. I interested myself in the *modus operandi*, and found the effect produced by retouching the negative with carmine, and this could only be effected by certain artists; they not only improved the faces but added backgrounds, all backgrounds being plain in those days. I became an expert in this kind of work, and hearing it was unknown in Germany, departed to Berlin. My specimens procured me instant employment with the then leading photographer, G. Schower. Here I first found pencil retouching performed by a French artist; we exchanged ideas, and much to my advantage. The autumn came, and my carmine retouching failed to give satisfaction, the prints became spotty. The cause could not be discovered, and I was compelled to fall back on the pencil. I wrote to Italy for fresh materials, but with no better result, and eventually discovered my method would not work in a damp climate. On my arrival in England I found pencil retouching universally practised, and in many cases with very pleasing results. I cannot state who invented pencil retouching, but several Frenchmen claim the merit. Mr. Josti then gave some practical illustrations of the treatment of a head, together with some examples of fancy retouching, and concluded his address with remarks on Rembrandt and Doré pictures.

An unanimous vote of thanks was passed to Mr. Josti.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of this Society was held at the Greyhound Hotel on Wednesday evening, April 27.—Mr. Brown in the chair.

STORING NEGATIVES.

Mr. WOLFF explained a new method of storing negatives which has three distinct advantages over the old system of grooved boxes, namely, saving of space, this method requiring but one-third the room necessary for the orthodox boxes; secondly, a particular negative can be quickly found from amongst a large number; thirdly, the cost is less than half the price of grooved boxes. The method consists simply in separating the negatives with sheets of paper cut to the exact size of the negatives, the four corners of each sheet having small triangular pieces of card glued on them to prevent the negatives pressing against each other; each dozen negatives with these intervening leaves are placed in a stout card box with hinged lid and falling front. On the back of each box is a label with spaces for number of box and names of twelve negatives.

ENLARGING ON BROMIDE PAPER.

Mr. Wolff next showed a curved support for bromide paper in making enlargements. By means of this case the bromide paper is made to take a curved form for the purpose of obtaining good definition at the ends of the paper without the use of small stops, the object being to reduce the time necessary for making the exposure. By the use of this curvature the exposure can be reduced to one-fourth or one-eighth of the time required with a small or medium stop. A developer consisting of pyro, potash, and ammonia, was described by Mr. Wolff, who showed specimen negatives and pointed out its advantages. In the use of it he first applies the bromide and pyro* to the exposed plate, next the carbonate of potash, and lastly the ammonia. Negatives thus developed have the cleanness and detail usually obtained with potash combined with the vigour given by ammonia. The chances of fogging during long development is greatly reduced by this method. Mr. Wolff showed some Eastman-Walker stripping films developed by this method which were excellent, and he particularly recommended workers using these films to try his method of development.

On Wednesday, May 11, there will be a lantern exhibition of members' slides.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting was held in the Technical Schools, Bridge-street, on the 28th ultimo.—Mr. W. J. Harrison in the chair. Forty-nine members present.

The minutes of the last meeting having been duly read and confirmed, Messrs. A. Constantine and A. W. Robinson were elected members of the Society.

A large number of photographs were exhibited by Messrs. Harold Baker, A. Bouchill, Dutton (stripping films), Harrison, Karleese, Pickard, and Thomas Taylor.

The excursion on May 7 was arranged for Lichfield, Mr. A. Pumphrey to be leader.

Mr. Nock then gave his paper on *Retouching*, remarking that too much retouching frequently spoils the picture. In many cases, even of professional work, the finished print was nothing like the person taken. For his own part, he preferred only retouching enough to relieve the shadows and soften the high lights. In cases such as freckles and people who were apt to show a contracted scowl there must be retouching; then flat pictures, by a similar method, can be made to look rounder in the features, &c. He then threw an enlarged picture (by means of the lantern) of a bad negative on to a tissue-paper screen, and proceeded to work it up by crayons, and showed how retouching should and should not be done. Some half dozen examples were very effectively altered, and the lecturer concluded by offering his practical advice at any time to the members.

Mr. PUMPHREY then read a paper on *Card-Mounted Flexible Glass Films* [see page 276].

* For pyro the Platinotype Company's preparation is used.

An animated discussion followed on both papers, and the meeting terminated with the announcement of the paper for next meeting, *Reminiscences of Photography*, by Mr. W. Osborn.

GLOUCESTER PHILOSOPHICAL SOCIETY.

PHOTOGRAPHIC SECTION.

THE annual exhibition and *soirée* was held at the School of Science on Tuesday, April 26, a large muster of members and friends being present, including some members of the Cheltenham Society.

The photographs on view numbered about three hundred and twenty, comprising views in Norfolk and Suffolk, by the President, G. Embrey, F.C.S.; in Norway, by J. W. Barnett; in Cornwall, by J. M. Collett; in North Wales, by F. H. Burr; in Mid Wales, by F. J. Hamblby; in Derbyshire, by W. J. Jenkins; South Coast, by S. F. Morse; and many others of local interest. These were shown in the Museum, together with enlargements lent by Messrs. S. Fry & Co.; roller slide, film negatives, and bromide prints, from the Eastman Company; and apparatus by many other firms.

The lantern slides, one hundred and twenty in number, were shown in the Lecture Room at two periods of the evening by the limelight.

The President of the Philosophical Society, Rev. E. G. Penny, in moving a vote of thanks to the Section for the evening's entertainment, congratulated the members on the excellence of their work.

GERMAN PHOTOGRAPHIC SOCIETY OF NEW YORK.

ON March 23, at 62, East Fourth-street, the above Society held their annual meeting, at which the election of officers took place. The following gentlemen were elected unanimously:—*President*: G. Mildenberger.—*Vice-President*: C. Buehler.—*Recording Secretary*: J. Esselborn.—*Corresponding Secretary*: G. Weinig.—*Financial Secretary*: L. Schill.—*Treasurer*: G. E. Pellnitz.—*Archivers*: L. Burkhardt, G. Bilgenroth.—*Trustees*: Charles F. Kutscher, L. Nagel, and A. Baumgarten.

Correspondence.

✂ Correspondents should never write on both sides of the paper.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—Had your correspondent, "Not a Portrait Photographer," confined himself to a fair statement of what I had written, I should not have troubled writing to you again, but, with your permission, I cannot allow him the license he has taken without demur, and would preface what I have now to say with the remark that when one correspondent, in order to make a point and prove what he may consider his argument, descends to the meanness of garbling another writer's statement, the cause he advocates must surely be a weak one.

Where have I said anything so ridiculous as "because types are 'plant,' and types may be and are used for the printing of many things, therefore they do not belong to the author;" or, "because a portrait negative can only be used for the printing of the portraits of one person, therefore it must belong to that one person—i.e., the sitter?" What I have said, and the meaning I have sought to convey is, that because authors are not usually charged with the cost of the types as types, but only for the "composition" or "setting" of them, therefore they are not entitled to their possession, and because it is the usual custom of photographers to charge the cost of the production of the negative in the charge made for finished prints, therefore the negative is undoubtedly the property of the person who has paid for its production.

Is it not a fact—I assert it is such, but am open to correction—that photographers charge in their first price for prints the cost of the glass and all the chemicals and subsequent operations necessary for the production of the negative? If they do, what are the grounds upon which their claim is made to property in the negative? It seems to me, to use a vulgar phrase, they seek to have both "the cake and the halfpenny."

I admit all "Not a Portrait Photographer" says with regard to the possibility of "cleaning the glass upon which a negative has been taken, and that the silver thereon can be recovered and utilised in the production of other negatives;" but what I would ask is, is it a commercial practice amongst portrait or any other photographers to do so? If it is not—I say it is not a commercial custom to do so, but again am open to correction—the sophistry of the argument of "Not a Portrait Photographer" is at once apparent.

As to the supposititious case your correspondent puts of a "printer having sufficient faith in the coming success of a literary effort to warrant him in stereotyping a work on the chance of being called upon to print a future edition, and because those stereotypes can only be used for the printing of that particular work that therefore they belong to the author," really, the abandoned imbecility of such a proposition does not merit serious consideration.

I am sorry "Not a Portrait Photographer" does not see the application of the ruling in *Foster v. Ward*, and gets mixed in his reference. The offer of payment for the stones is not by any means a tacit acknowledgment that the first payment does not include the right to the drawings (not negative). It is exactly the reverse. It is an assertion that the

drawings are not the property of the printers, and that the drawings being of much greater intrinsic value than the stones upon which they have been produced, the stones are equitably the property of the owner of the drawings on tender being made of the value of the stones in their clean condition.

The bearing of this ruling upon the pretensions of photographers may be seen in its full force when it is had in remembrance that a "sitter" is charged for the glass in the price paid for the prints.

As to custom in the printing trade respecting copperplates, my experience is just the opposite of "Not a Portrait Photographer."

The impertinence of the "advice," and the "superior person" tone of the first and last paragraphs of "Not a Portrait Photographer," is not commendable, and does not by any means assist his argument; however, in saying that, he will allow me to further say that I am at one with him in admiration of the meaning and practice of "*Ne sutor ultra crepidam*."—I am, yours, &c.,

G. A. RATTRAY.

28, Brown-street, Manchester.

To the Editors.

GENTLEMEN,—I am certainly not surprised at the silence of photographers generally when their claims to the ownership of portrait negatives is questioned, a claim which few would dare to uphold. That few who have written in your columns have not advanced one reason to substantiate their claim.

Mr. Barber admits that he is not a high authority, in which I assuredly agree with him, and his admission gives me some hopes for his future career.

Mr. Rattray's letter I read with pleasure. Authority or no authority, he placed the question in a fair and honest light. Mr. Rattray deserved better treatment than was given him by the writer who signed himself "Not a Portrait Photographer." Sneer is not argument, and had that writer remembered the old adage, "Example is better than precept," he would not have written the last paragraph of his letter, and in reference to which I would ask, Have the public, no matter what trade or profession they may be, no right to question an unjust claim made upon them? It is by their money portrait photographers live.

I do not say hand over the perfect negative to the client; I advocate its destruction. Let the portrait on the glass, which is not the photographer's, be destroyed, and the question of the ownership of the glass and silver film will then not be disputed. The contract would in this way be fairly and agreeably completed, the photographer paid for his work and his client supplied with the number of copies ordered.

The destruction of the negative would, in my opinion, add to the interest of the photographs. Lack of knowledge of the nature of the negative alone has allowed the custom for the photographer to retain the negative ever to exist.—I am, yours, &c.,

J. F.

Falcon-street, Newcastle-upon-Tyne, April 30, 1887.

DEAL PIER.

To the Editors.

GENTLEMEN,—The reason assigned by the Piermaster of Deal Pier to myself varied somewhat to that of your correspondent, as stated in your issue of April 22, that "The local photographers had represented to the authorities that amateurs, by photographing from the pier, were causing injury to their business—hence the impost," and cannot be correct, because at the period, now some three or four years ago, I was photographing for one of the local photographers (Mr. Berryman), and then there were but three in Deal. I offered the Piermaster the business card of Mr. Berryman and he most distinctly told me that Mr. —, another photographer, paid the authorities a fee, or else hired from them the right to take photographs from the pier, but that for half a sovereign I could go on one whole day. But at the same time it is most singular that a London publishing firm should only last week have paid, and I was also regaled with the story of the amateur's dark slides being opened and the plates spoiled by exposure to light.

It is, therefore, very evident that these two stock tales do duty very often, like the guide's story or yarn at old romantic places like Holyrood, Melrose, &c.

While there is life there is hope; and so at Deal, for right away from the pier to Walmer Castle (where the first Duke of Wellington lived the latter part of his life and where he died) are to be found any number of charming sea and shore studies.

I regret to say both Deal and Walmer Castles are disappointing from an artistic point of view. At Walmer the old doorway (portcullis), drawbridge, with the moat, and half-round tower partially covered with ivy, make a picture well worth the walk from Deal.

For sky pictures and cloud negatives, there are many quiet spots after passing the Barracks, and, as the high road runs along the seashore, or parallel with it, a visitor might stay on the sands all day and hardly any one pass in front of the camera. Mr. H. P. Robinson has, I know, made some of his most successful seascapes from along this piece of shore; in fact, the whole place is an haven of rest, a *dolce far niente*. "Deal is so comparatively little visited as a pleasure resort," BRITISH JOURNAL OF PHOTOGRAPHY, No. 1407.—I am, yours, &c.,

ARCHER CLARKE.

8, Suffolk-place, Wandsworth, S.W.

COLONIAL AND HOME GRIEVANCES.

To the EDITORS.

GENTLEMEN,—The letter by Mr. Cooper is interesting and useful; one must agree he has been badly treated. But why did he not return the camera as a fraud, and if not paid his money back or supplied with a perfect article, see what effect a County Court judge would have in the matter?

I think it is a capital plan to use (if so allowed) your valuable JOURNAL to expose deceptions. I have noticed the useful *C. T. C. Gazette* has done good service to cyclists in a like manner.—I am, yours, &c.,
West-End Studio, Alton. GEORGE FROST.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

- I will give a good arguette for a view lens.—Address, W. SAUNDERS, Dickleburgh, Scole, Norfolk.
Exchange, a Ross' 12×10 view lens for a rapid rectilinear, same size.—Address, DIXON, Photographer, Colne.
Two good Lancaster view lenses of twelve-inch focus for one of nine-inch focus by a good maker.—Address, S. 555, Battersea Park-road, S.W.
Wanted, a large roll press or grass mat and good background, for useful half-plate lens. Difference in cash.—Address, G. FROST, Alton, Hants.
Large C.-D.-V. portrait lens, by Vogel, with Waterhouse diaphragms, will exchange for landscape or group lens.—Address, Mr. ASHLEY, Photographer, 29, East-street, Hobart-street, Plymouth.
Will exchange a cabinet rolling press and silver English lever watch, value £5, for tricycle, with ball bearings, which would carry photographic outfit.—Address, D. KENNEDY, Photographer, Invergordon, N.B.
Will exchange half-plate hot rolling press, centre pressure, also changing bag to fit on tripod, chemicals, porcelain dippers, and a half-plate sliding-body camera with double dark slide; wanting, 12×10 bellows camera with screw adjustment.—Address, GRAVES, Photographer, Lutterworth.
Camera, 12×10, bellows body, twenty-four-inch focus, two dark slides for wet plates 9×7, one quite new, to take two cabinets and two C.-D.-V.'s; also one dark slide (quite new) for 9×7 double cabinet and two C.-D.-V.'s; also one 12×10 slide with carriers down to quarter-plate, in good condition. Will exchange for a Dallmeyer's 5D lens.—Address, DODGE & Co., 170, Union-street, Plymouth.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

- W. E. DALTON, South-street, Moor, Sheffield.—Photograph of a wreath of flowers, including the words, "The Queen's Jubilee."
John Owen, Newton, Montgomeryshire.—Two photographs of the house in which the first Sunday School was held.
Thomas Ball, 7, Comberton-hill, Kidderminster.—Photograph of group of ladies in fancy costume.
T. A. Moryson, Dumfries.—Two photographs of a girl with gloves.

MECHANIC.—You are mistaken; collotype printing by machine is being practised in this country.

A. B. R.—You will find an article on the subject in the last edition of Harwich's *Photographic Chemistry*.

C. J. DONNS.—The negative sent is very good, being sharp and clean, and well adapted to the purpose required.

MEDIUM.—The only work on the subject is that by the late Mr. Joseph Wake, but it has long since been out of print. It is quite possible that you might obtain a copy by means of an advertisement.

C. C.—White-hard varnish diluted with methylated spirit makes a fairly good varnish for negatives, but brown-hard is much better, so far as durability is concerned, but it is somewhat darker in colour.

W. W.—Under the circumstances we should advise you to make your background by the "powder process" instead of in flatted oil colour. Unbleached sheeting can be obtained at most of the linen drapers.

T. COAN.—From the behaviour of the plate it is clear there was something wrong in the development, but what it is impossible for us to say. If the solutions had been the same as mentioned a widely different result should have been obtained.

C. F. HEWETT.—Get a plano-convex lens of about ten feet focus and twelve inches in diameter. The focus of the lens must determine the height of the dome. Let the mirror exceed in size the diameter of the lens, and be half as long again as its width.

G. Y. G.—The transparencies are interesting, but as you do not say how they are produced we cannot express any opinion as to their novelty. Silver pictures toned with platinum are common enough, but perhaps yours are not produced by this method.

R. C. CURTIS.—We cannot say by simply looking at the mounting boards whether they contain anything that is likely to act injuriously on the photographs. This can only be determined by chemical analysis. Any analytical chemist will make this for you.

SEPTIMUS.—The most prolific cause of the washing away of the delicate tints of a carbon print during development is that of the tissue being in a too soluble condition. This may be avoided by keeping the tissue several days before using, or to dry it more slowly after it is sensitised. Either of these plans tends to induce insolubility.

PROFESSIONAL.—A rapid symmetrical lens will do very well indeed for taking large heads, but it will be somewhat slow for taking portraits of children. For this purpose a lens of the portrait form is far preferable. We cannot undertake to express an opinion on the cheap kinds of lenses; their merits often vary with each individual instrument.

FAIR PLAY IS A JEWEL.—This correspondent complains that a certain Company shows favouritism in supplying their customers. He says that some persons can obtain a supply of material with promptitude, while others are kept waiting, or are "left out in the cold." We do not see that we can assist our correspondent further than by sending his communication to the firm concerned, and thus we have done.

NEMO says: "Will you kindly tell me the best bath and developer for easy manipulation in taking positives upon glass?"—Silver bath:—Nitrate of silver, thirty grains to the ounce of water, rendered slightly acid with nitric acid. Developer:—Water, one and a half pints; protosulphate of iron, one ounce; glacial acetic acid, one and a quarter ounces; nitric acid, half a drachm; alcohol, sufficient to cause the solution to flow over the plate easily.

W. M. L. writes as follows: "I have just built a room for the double purpose of plate making for our own requirements, and also, in the busy part of the year, a waiting room. I have lined it with match-boarding, varnished, which of course is shiny and reflects light to a certain extent. We have glazed it with a perfectly non-actinic light for plates, but find they fog. Would the still slight reflection, although the light admitted is all right, affect the plates?"—In reply: If the light admitted by the windows be perfectly non-actinic, the reflections from the walls of the room will do no harm to the plates. But in all probability the glass is not so. It must be borne in mind that a light may be so non-actinic as not to fog a plate exposed to it for a short time only, as during the development, but the case would be widely different if the exposure was several hours, as when the plates are being dried. During this period all light whatever should be excluded.

W. B. CASSINGHAM says: "I have purchased a quantity of sensitised paper from a certain firm; on opening it I found it to have a most disagreeable smell. Not having had paper perfumed before, I would like to have your opinion of it in your 'Answers to Correspondents' columns; is it likely to interfere with the permanence of the prints? I have also a quantity of toning solution that I mixed up about six months ago (acetate of soda bath); I always keep a cardboard cover over the bottle, but it has gone very dark—almost black when viewed in the bottle, which holds four pints; is this right or should it remain clear?"—Opinions appear to differ as to whether paper with an offensive smell yields more fugitive prints than that prepared with fresh albumen. The general idea seems to be that there is practically no difference. With regard to the toning bath, the discoloration is due to a reduction of some of the gold—a very likely thing to occur after so long keeping. A fresh addition of gold and filtration will no doubt set it all right.

DON GUILLERMO writes: "Would you kindly give me, in your 'Answers to Correspondents,' a formula for sensitising the blue ferro-prussiate paper used for making prints and moonlight effects, and also state what is the best paper to use?"—In reply: Any fine quality of wove paper will answer. The Saxe or Rives photographic papers are as good as any that can be employed. With regard to the formula for the sensitising solution, full details for the preparation and employment of the paper will be found on page 831 of our last volume. The sensitising bath is as follows:—One ounce of red prussiate of potash is dissolved in eight ounces of water, and one ounce of ammonia citrate of iron in two and a half ounces of water; when required for use the two solutions are mixed in the proportion of one part of the iron solution to two of the potash. We cannot undertake the business mentioned in the latter portion of your communication; some of the stock dealers will no doubt carry out your instructions in the matter. We advise you to put yourself in communication with one or other of them.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—There will be an excursion on Saturday, the 7th instant, to Chingford. The train leaves Liverpool-street Station (Great Eastern Railway) at three minutes past three p.m.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, May 11, 1887, will be *On Camera Stands*. Outing at Twickenham on Saturday afternoon. Meet at Twickenham Railway Station as near to half-past two as possible.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next ordinary meeting of this Society will be held on Tuesday next, May 10, at the Gallery, 5A, Pall Mall East, when a paper by Mr. J. B. Spurge will be read, being the second part of his paper read at the February meeting.

STELLAR AND STELLAR SPECTRA PHOTOGRAPHS.

THE Jubilee year of Her Majesty will be epoch marking in more senses than one: the spring of eighteen hundred and eighty-seven will ever stand prominent in the annals of astronomy as the period when the initiative of a completed, wide-reaching scheme of mapping the whole heavenly vaults was first taken. The great congress of astronomers collected together at the French metropolis met with the determination to work at the large idea till a thoroughly practical plan was evolved, and they have succeeded, as will be seen in the particulars which we shall presently detail.

It is to be understood that a number of observatories undertake to join hands in taking negatives of various portions of the sky—each its allotted portion—till none remains unphotographed. The results will all be tabulated, arranged, and measured so as to form a complete map, including every star up to a certain magnitude. That magnitude as now arranged is the fourteenth. This is a vast undertaking; but the labour being spread among many observatories, according to a pre-concerted scheme, there will be no great stress felt by any of the workers. It is not yet decided whether ten observatories of the United States can accept the conditions of the Conference.

We must here draw attention to a series of observations, on parallel lines, on what can only be called a gigantic scale, which are being carried on by a single observatory in the States—we allude to the photographs of spectra of stars now being produced at Harvard College as a memorial of the late Dr. Henry Draper. As at present arranged, the scheme embraces no less a project than the obtaining and cataloguing of photographs of the spectra of every "star north of -24° of the sixth magnitude and brighter, a more extensive catalogue of stars brighter than the eighth magnitude, and a detailed study of the spectra of bright stars." It is hoped that ultimately a Southern station will also be selected, so as to embrace all visible stars up to the dimension named.

The points most interesting to the photographer will naturally be the lenses and the processes—the plates. The Paris Conference has already decided upon the former, as also upon the principles governing the selection of the latter. For this star mapping refractors only are to be employed, and, after a considerable amount of discussion, it was decided that the aperture of the object glass shall be $\cdot 33$ metre, and the focal length about $3\cdot 43$ metres: this, our readers will observe, is about $\frac{1}{3}$. As to plates, it is decided that they should be prepared according to an identical formula to be subsequently determined, and that a "permanent control of these plates

from a point of view of their relative sensibility to the different radiations shall be instituted." So far as this information carries us, it appears to us to be an unfortunate decision. Any one who knows anything about plate making will be able to form some idea of the probability of plates prepared respectively in St. Petersburg, Paris, or the Cape of Good Hope, being in the slightest degree uniform according to the standard. We should have imagined a far better plan would have been to make the plates at one centre and despatch them to the various stations as required. The ten thousand plates spoken of would be taken in hand by any dry plate manufacturer (they would be a mere bagatelle), and uniformity guaranteed. The extent of field is to be at least one degree from the centre. There is also to be a supplemental catalogue with shorter exposures, "to assure a greater precision in the micrometrical measurement of the fundamental stars." The great usefulness of this idea will be readily perceived by the experienced photographer when he notes that while stars of the first magnitude only require an exposure of the two-hundredth part of a second, those of the fourteenth need thirteen minutes; so that the former would be exposed one hundred and fifty-six thousand times too long when the plate was exposed so as to obtain stars of the above minimum magnitudes as decided upon by the Committee. We think that they were wise in not including still fainter stars, as the sixteenth magnitude, according to the same authority—Admiral Mouchez—would need one hour and twenty minutes' exposure.

It is evident that to carry out all these plans a large number of new instruments will be required, seeing that object glasses of one particular diameter and focus only are to be made use of. "The estimated cost for each observatory, including instruments, extra assistants, plates, measurements, &c., is about four thousand pounds."

Turning now, again, to the Draper Memorial photographs, which, it will be borne in mind, are, for the northern hemisphere at any rate, to be produced at a single observatory, we find from the Report just issued, that the same rigid formality as to the lenses used is neither necessary nor useful. The first instrument used by Dr. Draper, in 1882, was simply a Voigtländer portrait lens of two inches diameter; this was followed by one of eight inches, and Albertype engravings from the negatives are given in the plate accompanying the Report. Five minutes' exposure in each case was given, no clockwork being used to follow the star as in telescopic work generally. Provided the exposure is not too protracted the value of this is

readily seen; the spectrum of so near an approach to a point as a stellar image is would naturally be merely a succession of bright and dark dots, but by allowing the image to move at right angles to this line of dots it becomes widened out into a ribbon as it were. In the later photographs a subsidiary arrangement to this intent is brought into play. For these spectra Dr. Draper's own eleven-inch photographic lens has been used, as also a fifteen-inch telescopic objective belonging to Harvard, and, finally, Mrs. Draper has decided to send also the twenty-eight-inch reflector and its mounting, this being the instrument with which his celebrated picture of the moon was taken. The first two instruments have been hard at work every night for several months past, and it is now intended that at least three telescopes shall be used during the whole night till the work is interrupted by daylight.

Fraunhofer's original method of producing the spectrum has been reverted to; it consists simply in placing a prism (or prisms) before the lens. Four prisms of fifteen degrees are employed at Harvard, each being bound with brass, and fitting like a drawer into a brass cubical box, so that one prism or the whole battery at will can be placed into action. Three prisms have a face of eleven inches, one being a little smaller, and the whole box weighs upwards of a hundred pounds.

The images of the spectrum are obtained at first upon a small scale, afterwards magnified, the utmost power of the light in obtaining an original image being thus utilised, every radiation, even the feeblest, impressing itself upon the plate.

The sensitiveness of the plates has been a difficulty with the Harvard authorities. They, wisely we think, tested a series of commercial plates, and decided upon a certain brand, and afterwards, finding a still quicker mode, they now use the latter. The Report states that "apparatus for testing plates, which is believed to be much more accurate than that ordinarily employed, is in course of preparation. It is expected that a very precise determination will be made of the rapidity of the plates employed." Should this expectation be realised, photographers may perhaps be gainers.

We have now said enough to show our readers that photography, as applied to astronomical science, has, by leaps and bounds, arrived at a position which, as we stated, will make the Jubilee year an epoch in the science, and our readers will join in our wish that the utmost success may attend these parallel undertakings in both hemispheres.

FIGURES IN LANDSCAPES.

"Why is it," inquired an artist at one of our photographic exhibitions, "that good, clever photographers will persist in spoiling their landscapes by the introduction of figures inartistically posed?"

There was some good reason for the protest conveyed in this question. Several landscapes having in other respects more artistic and technical merit than are to be often seen, certainly did possess the peculiarity complained of. We all know full well that a landscape is not unfrequently greatly improved by such figures; they impart a degree of life and character to a scene which without them might be cold and inanimate. But how few there are who seem to be capable of posing them aright. Some photographs in the exhibition alluded to came as near to perfection as can well-nigh be desired, but had their beauty clouded by obtrusive meaningless figures, introduced in the wrong place and looking in the wrong direction—more frequently towards the camera than anywhere else.

Technical photography is more easily acquired than a correct idea of art canons, and there is apt to be an abnormal straining after perfection in the former to the disregard of the latter. On attaining such perfection it is, perhaps, not unnatural that the photographer should seek to display his proficiency by submitting his works to public criticism at one or other of the numerous exhibitions now so readily accessible to the aspirant. But the public, too, are becoming alive to the fact that technical photography is not now the difficult thing it once was, and they are beginning to look in a photograph for other merits than those which are allied to the mere mechanics of the art-science.

It is by no means difficult to educate oneself in the composition of a landscape study to such an extent as shall leave no cause of animadversion for the most hypercritical of observers, and well would it be if the photographer who has acquired this degree of skill would abstain from proceeding further, as regards his public displays, until he had advanced further in his art education and mastered some of those canons of art and taste which bear upon the introduction of figure subjects which shall be in such *rapport* with the surrounding scenery as to be part and parcel of it. If it be not so, then may—nay, *will*—the whole effect of the picture be marred, like as in an otherwise perfect and complete orchestra one ill-tuned instrument acts detrimentally. But where they are properly introduced, figures are not only interesting in themselves but impart interest to a landscape. We do not here allude to subjects in which the figures form the chief theme, the landscape being merely subordinate thereto, but to pictures in which the landscape itself forms the *motif* and the figures the subordinates introduced to give sparkle and point where requisite.

This is so well expressed by Robinson in his *Pictorial Effect in Photography* that we cannot do better than give a quotation from this master in composition:—

"Before placing figures in a landscape, the artist should first make up his mind whether the composition requires the introduction of any subject to add to its completeness. If he does, do not let anything induce him to take the view without the figure, because he will be doing something that he can see could be done better with the assistance of a little more trouble; above all, he should avoid incongruity, and never, for the sake of pleasing a friend by putting him in the picture, introduce an element of discord. The figures should look so right where they are placed that we should have no suspicion that it would be possible to place them anywhere else. . . . The figures and the landscape should never be quite equal in interest or pictorial value. The one should be subordinate to the other. The pictures should consist of figures with a landscape background (if they are represented in the open air), or of a landscape in which figures are introduced merely for the sake of impressing a point or adding life to the more important scene."

It is almost tautological to add to the foregoing the following for the special benefit of those whose love for the technics of photography has permitted them to allow their art instincts to remain as yet in abeyance. Let figures, where introduced to enhance the value of a landscape, occupy the least important and weakest part of the subject as regards its interest; let them be placed on different levels if possible and in various and contrasting positions, and let them be subordinate to and aid the general sentiment of the landscape.

It seems impossible to many photographers to take a view embracing a country stile without placing it in the centre of the picture, and the obtrusive figure of the "friend" posed as if he or she were about to get over it.

Equally impossible does it seem to some to take a view of a river without giving an offensive prominence to the inevitable

fisherman, rod in hand. We have, however, known a good and suggestive picture having been produced by the fisher being asked to retire beyond the grasp of the lens, leaving the rod and basket on the bank to represent him.

GALLIC ACID AS AN INTENSIFIER.

RESUMING our experiments with gallic acid as an intensifier of gelatine negatives, we forsook entirely the comparatively useless formula to which we alluded in our previous article a fortnight ago. We first of all made up solutions according to the formula published by Jastrzembski some years ago, which will be found in our ALMANAC, but which for the sake of convenience we repeat here. The solutions consist of—

No. 1.

Gallic acid 1 part.
Alcohol 10 parts.

No. 2.

Nitrate of silver 1 part.
Water 16 parts.
Acetic acid $\frac{1}{4}$ to $\frac{1}{2}$ part.

For use, the gallic acid solution is diluted with about four times its volume of water, and a few drops of No. 2 then added.

This, it will be found upon calculation, forms a pretty strong solution of gallic acid as actually employed—nearly ten grains to the ounce in fact, a quantity of the acid it would be entirely impossible to detain in solution but for the alcohol. On the other hand, the proportion of restraining acid in No. 2 is remarkably small, being from seven and a half to fifteen minims of acetic acid to thirty grains of silver nitrate in each ounce of solution. The larger quantity of acetic acid if employed in conjunction with pyro would scarcely effectively prevent abnormal reduction, especially in a prolonged intensification; but with gallic acid, even though the latter be employed in strong dose, there appears little tendency to fog.

The action of this intensifier proceeds slowly, but regularly, the colour of the deposit being browner than when pyro is employed and its printing value greater. The final result is, in fact, most satisfactory, but the time occupied in the process is painfully and unpleasantly long even in comparison with pyro and silver intensification of gelatine plates, which is notoriously more prolonged than in the case of collodion. With such a liberal proportion of gallic acid to the ounce of solution one would at least imagine there would be greater energy, and we were at first at a loss to account for the extreme slowness of action, until it struck us that possibly the presence of a large proportion of alcohol (a total of twenty per cent.) might have something to do with the result. As our readers are well aware, alcohol has a powerful hardening action upon gelatine, especially in the moist state, and not only refuses to allow itself to be absorbed into the gelatine, but prevents the absorption of water, and when strong actually extracts the latter.

A feasible explanation of the slowness was found in the possibility that the combined hardening effects of the gallic acid and alcohol, together with the counteraction of the alcohol against the absorption of the solution by the film, was the real cause of the retarded intensification. Another troublesome effect of the alcohol is to be found in its tendency to cause uneven action, owing to the "greasy" manner in which the solution flows over the film when the latter has been previously dampened, or when the negative is washed after the

intensification is complete. For these reasons, therefore, we determined to try the effect of an aqueous intensifier.

In this case it is impossible to employ a solution of anything like the same strength as that of Jastrzembski, for, as is well known to old paper or albumen process workers, gallic acid is only soluble to the extent of about three grains to the ounce of cold water, though much more so as the temperature rises. We suspected, however, that this strength might prove quite as effective as the higher quantity when the check action of the alcohol and the stronger hardening effect of the ten-grain solution were removed, and in this, as will be seen subsequently, we were not far wrong. If, however, a stronger solution be required without the introduction of alcohol, the addition of a little glycerine will increase the solubility of the gallic acid though not to the same extent as alcohol. The glycerine has also another beneficial action, inasmuch as it increases instead of diminishing the penetrating power of the solution, and so goes far to help the intensifying process; and, lastly, as we shall show in our description of the method of manipulation, by increasing the fluent properties of the solution it enables the operation to be performed without the aid of a dish, an advantage the importance of which will be pointed out.

The solutions we employed were as follows:—

No. 1.

Gallic acid 20 grains.
Glycerine 1 ounce.
Water 5 ounces.

No. 2.

Silver nitrate 120 grains.
Citric acid 30 "
Nitric acid 30 minims.
Water 4 ounces.

Dissolve the gallic acid in the water, hot, add the glycerine, and when quite cold filter. The glycerine we employed is a cheap foreign sample, costing something like tenpence a pound retail, absolute purity being apparently a matter of no moment. For various reasons we prefer citric acid to acetic acid, one of the chief being that it is a more stable substance and of uniform strength. The nitric acid we invariably use with silver intensification on account of its special action in keeping the intensifying solution clear and preventing deposit. In case of a preference for acidifying the gallic acid solution—a practice which some prefer since it enables the operator, by applying it to the plate before adding the silver, to neutralise any traces of alkali left from the developer—the following modified formula may be employed, the solutions being—

No. 1.

Gallic acid 20 grains.
Citric acid 2 to 3 "
Glycerine 1 ounce.
Water 5 ounces.

No. 2.

Silver nitrate 120 grains.
Nitric acid 30 minims.
Water 4 ounces.

If it be desired to use acetic acid instead of the citric, the former may be substituted in the proportion of about fifteen minims of the "glacial" acid for each half grain of citric acid; or, say, two ounces in the first formula, and from one drachm to a drachm and a half in the second.

As we have already hinted, upon testing this modification, although only one-third the strength of Jastrzembski's, it

proved to be not only as powerful in action, but more rapid. Though, perhaps, not so quick in its effects as pyro under similar circumstances, the difference is not great, certainly not sufficiently so to forbid the substitution of gallic acid should it prove to possess other advantages, which we think it does. One of these is a greater freedom from tendency to stain the film after prolonged application, as pyro frequently does, though it must be borne in mind that the stain so produced, if not partially due to unremoved hypo, is more readily got rid of by alum and hydrochloric acid than that which results from alkaline pyro. Another apparent advantage consists in the better colour usually obtained with gallic acid, and the greater density obtained. When pyro is employed, for some reason or other the negative will occasionally refuse to gain density, however long the application may be continued, or in spite of the quantity of silver added. This we have never noticed in connection with gallic acid, for, though the action may in some cases be exceptionally slow, the effect, if gradual, is always certain. As in the case of pyro intensification, the density invariably increases on drying the negative, a fact which should always be held in view.

Allusion has been made to the desirability of dispensing with the use of a dish in intensifying, and this the presence of the glycerine, by causing the solution to flow readily over the usually somewhat repellent gelatine surface, enables us to do. The gain is in the direction of economy, as a couple of drachms of solution will answer for a half-plate, when with the dish as many ounces would be required, meaning the expenditure of eight times the quantity of material, besides which the back of the plate does not require freeing afterwards from the deposited silver.

In using it, from three to five minims of solution No. 2 are added to each drachm of No. 1, poured on to the film, and kept in motion until the necessary strength is obtained, after which the plate is well washed, then soaked for a few minutes in a strong solution of common salt or iodide of potassium to remove any traces of free silver, and finally again washed before drying.

At the last meeting of the Quekett Microscopical Club, a paper upon a new photo-micrographic camera was read by Mr. E. M. Nelson, which was of a rather notable character, seeing that he claimed for his invention that it was "not a makeshift which is only capable of doing fairly good work, but it is proved by practical experience to be equal to the highest class of work;" and this, too, notwithstanding the fact that "the whole of the apparatus, namely, camera, microscope, lamp, is produced at a cost less than is usually paid for a camera alone." As far as we can gather, the chief point of novelty about the new arrangement is the employment of the Zeiss projection eye-piece in lieu of the ordinary eye-piece. The camera itself is simple and neat, and adds one more excellent form to the list of existing useful patterns familiar to workers in this direction. It consists of two cardboard tubes, one sliding into the other, and the junction protected by a velvet flap; the wider tube is attached to an upright board with an aperture, behind which are placed grooves to receive ground-glass or dark slide, metal slides being recommended. This upright board is attached to a baseboard which holds the microscope (to be placed horizontally) and the lamp. The fine adjustment is worked by a string passing first over a long rod placed at the side of the baseboard, then over the head of the adjustment screw, and, finally, over a pulley on the other side of the board.

It is thus seen that a neat and simple arrangement, which any one can make for himself, is here indicated. The advantage of using an eye-piece is undoubted in the direction of convenience; and if this new eye-piece prove to possess decided advantages over the ordinary

form, it is highly probable that photo-micrographic work in future will not be produced by the objective alone. For those whose space is limited there is great convenience in its use, from the distance between ground-glass and object being restricted to such narrow limits.

We have had considerable experience in this kind of photography, and the conclusion we came to at an early date was that the chief secret of success lay in the illumination of the object to be photographed. In microscopic work generally the same remark may be made, and we unhesitatingly say that no one is likely to succeed in photo-micrography in various directions, unless he have some experience with the requirements, and the possible varieties, of microscopic illumination. We observed that at a recent meeting of the Royal Microscopical Society, one of the Fellows exhibited some photo-micrographs as the result of an alteration of the illumination, in the direction of cutting off superfluous light by means of a sliding diaphragm. With regard to this, we must say that in all projections, whether lantern or microscopic, the nearer the illuminant is reduced to a point (a form of expression exchangeable with "cutting off superfluous light") the more delicate and sharp does the definition become.

We referred lately to the indefiniteness of popular nomenclature in the case of the carbonates of soda, and also to the possibility of change taking place in the substance itself, and in a recent number of the *Comptes Rendus* of the Paris Academy of Science allusion is made to a singular property of one of the many forms of this substance. The author of the observation, M. Paul de Mondésir, has observed that sodium carbonate if combined with a single equivalent of water absorbs carbonic acid extremely slowly, if at all, at ordinary temperatures, while if it be mixed with a small quantity of bicarbonate the reaction sets in at once, and with an energy proportionate to the quantity of the bicarbonate present. It is evident that this monohydrated salt would be a most useful one for the photographer, as there would be little liability to fluctuations of strength, although if it were used it would be necessary to remember that an allowance would need to be made in the formulae employed for the increased strength of the new in proportion to the more usual forms of the salt.

We believe that owing to the uncertainty we allude to, the number of photographers using the "bicarbonate"—i.e., the hydrogen sodium carbonate—for developing is by no means few. It is, of course, impossible to tell what proportion, if any, of neutral carbonate, which would facilitate the development, is contained in their samples; but it is not difficult to ascertain whether any of the latter be present or not. If a little rosolic acid be added to a concentrated solution of the bicarbonate, no change will be perceived even after the lapse of a quarter of an hour; but if from one to four parts in a hundred of neutral carbonate be present a rose tint is quickly produced; when a still larger quantity is present the colour becomes more of a purple.

THE NEWCASTLE-ON-TYNE PHOTOGRAPHIC EXHIBITION.

In the Jubilee Exhibition which was opened in Newcastle-on-Tyne, on Wednesday, there is a very imposing and attractive Fine Art Section, and a really excellent Photographic Section. In this latter there are sixty-four exhibitors (of whom twenty-four are amateurs), the total number of frames being a little over three hundred. Although situated so far north, yet do our Scottish brethren seem to have held aloof, there being, so far as we can perceive, only three exhibitors from the Northern Kingdom. The pictures, whether landscape, portrait, or *genre*, are all of a high class. The gentlemen selected to act as judges of the awards included as one of their number a local professional artist of recognised ability, Mr. H. H. Emmerson, President of the Bewick Club.

To one who has visited other photographic exhibitions of a past period, many of the photographs will be familiar as old acquaintances, but there are also many which we have not met with before, and which appear here for the first time.

Among the exhibitors of portraits are Ancrum & Son, Bruce, W. Winter, Werner & Son, Mendelssohn, Lafayette, Byrne, Bruton,

Parry, Spencer, Chaffin, P. H. Emerson, Hingley, Hogg, Thompson & McLeish—names the most of which are associated with high art excellence.

In landscape work the collection is very rich. J. P. Gibson's series, *An Autumn Evening on the South Tyne* (140), and others by the same artist are above average. M. Auty, too, shows good work. J. Pike has a fine display, including well executed views of old buildings in Newcastle. The exhibits of Harry Tolley arrest attention; several of them have been taken in the attractive dells of Derbyshire. The subjects in the landscape department are of as varied a type as can be desired, for we find Norwegian and Welsh mountain scenery (by Ellerbeck), Norfolk scenery (by Emerson), hanging in happy proximity to Jesmond Towers, Derwentwater, Cornish, Yorkshire, Surrey, and other county scenery. P. M. Laws & Son exhibit a frame of well executed ceramic enamels, the only specimen of photo-mechanical work in the Exhibition, a careful piece of photo-lithography being contributed by the same firm. One sees, with much pleasure, the technically perfect views of Spanish interiors by A. Pringle. W. H. Geddes & Son have effective snow scenes.

There are none among the local photographers who will not be gratified at being afforded an opportunity of examining the *Dawn and Sunset* of H. P. Robinson, the *Water Rats* of F. M. Sutcliffe, *West's Yachts*, and other photographs of celebrity of which they have read or heard.

The display by local photographers is most creditable, and is such as to show that they need not fear competition by outsiders. In regard to either artistic or technical qualities, Newcastle and the surrounding country produce photographers of which the whole fraternity may be justly proud.

The following are the medal awards:—

JUDGES' AWARDS.

Class I. Series of six portraits.—J. Lafayette, Dublin, gold medal; H. S. Mendelssohn, London, silver medal; Werner & Son, Dublin, special mention.

Class II. Series of six landscapes.—H. Tolley, Nottingham, gold medal; Paul Lange, Liverpool, silver medal; J. P. Gibson, Hexham, special bronze medal; F. M. Sutcliffe, Whitby, special mention.

Class III. Single landscape or marine.—H. R. Procter, Tynemouth, silver medal (landscape); J. Pike, Newcastle, special bronze medal (marine).

Class IV. Figure.—F. M. Sutcliffe, Whitby, silver medal.

Class V. *Genre*.—F. M. Sutcliffe, Whitby, silver medal; A. Diston, Leven, Fife, special mention; A. Donald, Dundee, special mention.

Class VI. Ceramics.—P. M. Laws & Son, Newcastle, silver medal.

Class VII. Enlargements.—M. Auty, Tynemouth, silver medal; J. H. T. Ellerbeck, Liverpool, bronze medal.

Class VIII. Instantaneous.—H. Symonds, silver medal; E. W. Habone, M.D., London, bronze medal.

Class IX. Architectural.—J. Pike, Newcastle, silver medal.

Class X. Interiors.—W. Parry, South Shields, silver medal.

Class XI. Photo-mechanical.—P. M. Laws & Son, silver medal.

Class XII. Amateur.—P. Lange, Liverpool.

On the suggestion of the Jurors a special bronze medal was awarded to Mr. Adam Diston by the Council for his picture, *The Smithy*.

THE ABC OF PHOTOGRAPHIC EMULSIONS.

[A Communication to the North London Photographic Society.]

HAVING chosen as the title upon which to base my remarks "The ABC of Photographic Emulsions," I do not need at the outset to explain that my object is not so much to demonstrate to you any process of practical emulsion making as to explain the general principles which are common to every process, and give a general outline of manipulations necessary for their production.

Let us first decide upon what we mean by a photographic emulsion. Every schoolboy knows that the word emulsion is derived from the participle of the Latin verb *emulgere*, "to milk out;" and the dictionary definition of it will be found to run thus: "Any milk-like mixture prepared by uniting oil and water by means of another substance, saccharine or mucilaginous." It is obvious, however, that this definition will not apply to an emulsion in a photographic sense. In this sense a more correct definition would be: "A viscous fluid holding in suspension a substance in a fine state of division."

As an example, let us suppose that a quantity of a substance in fine powder—common whiting for instance—be stirred into a glass of water. At first we should have a mixture having all the appearance of an emulsion, but in a short time the particles of chalk would

subside, leaving the water clear. If, however, instead of water, a solution of gum or gelatine were used, the chalk would be held in suspension for a considerable time. This would be, from a photographic point of view, an emulsion, though of course it would not be a sensitive emulsion.

Sensitive emulsions usually consist of bromide, iodide, or chloride of silver, or a mixture of them, suspended in a solution of gelatine or in collodion. These three haloid salts of silver have many characteristics in common, and are usually produced by the admixture of a solution of one of the soluble bromides, iodides, or chlorides, such as those of ammonium or potassium, and a solution of nitrate of silver.

As an example, I will take a solution of bromide of potassium and add to it a solution of nitrate of silver. That a chemical change has taken place is at once evident. The insoluble bromide of silver will quickly find its way to the bottom of the vessel, leaving the other resultants of the double decomposition in solution. [The lecturer here explained the equation,

For most purposes it is necessary that the soluble nitrate should be removed. In the present case this may be effected by simply washing the silver bromide in a few changes of water. If after this treatment we add the silver bromide to a solution of gelatine, we have a gelatino-bromide emulsion.

An emulsion made exactly in the way I have demonstrated would not be found to be a satisfactory one, for reasons which I shall explain hereafter; but there are several practical processes in which the silver bromide is obtained as a precipitate, washed, and emulsified. These are known as precipitation processes.

It is one of the laws of chemical combination that the same compound invariably contains the same constituents and in the same proportions. The same compound, however, may exist in forms physically very widely different; Derbyshire spar, marble, and chalk, for instance, are all carbonate of lime, but in different molecular conditions. In the same way the silver haloids may exist in different molecular forms, the particular form in which they appear being governed in the first place by the conditions under which they are produced, the original state, however, being amenable to alteration by after treatment in a variety of ways. It is to this fact we owe the power of producing emulsions which differ in sensitiveness and in other important particulars.

In the last experiment the silver bromide was formed very rapidly and in very coarse particles. It has, however, been generally agreed that, although certain desirable qualities in an emulsion are only present when the silver haloid is in apparently coarse particles, this condition must be the result of after treatment, and that the silver haloid must, in the first place, be produced in a finely divided state. One of the factors in producing this fine division is the rapidity with which the particles are formed, and a little consideration will make it evident that the viscosity of the fluid in which they are formed will exercise a powerful influence in this direction. There are, besides, other factors, all of which it is of the utmost importance to take into consideration in practical work, such as the presence, during the formation of the haloid, of an excess of the silver salt or of the bromide salt, the acidity or alkalinity of the solutions, the temperature at which the mixture is made, and the method of mixing the various constituents.

As an experiment I will now proceed to make a small quantity of emulsion by the following formula:—

Bromide of potassium	15 grains (14+1),
Nitrate of silver	20 "
Gelatine	20 "

to one ounce of emulsion.

It is not, however, to be understood that this formula, or that the method I am about to adopt in this experiment, is to be recommended for practical work. It is, in fact, one of the earliest published, dating from long before dry plates of the sensitiveness of those of to-day existed, except in the visions of enthusiasts.

We have here twenty grains of nitrate of silver. To convert the silver of this into bromide will require fourteen grains of bromide of potassium; there is, therefore, an excess of one grain of bromide of potassium. I may here mention that collodion emulsions may be made in which there is an excess of silver nitrate, but this is not practicable with gelatine, as a chemical combination is entered into between the silver and the gelatine producing fog.

Following the course usually pursued, having soaked the gelatine in cold water, I dissolve it and the potassium bromide in a portion of the water, using the remaining portion to dissolve the silver nitrate. The silver solution is now to be added to the gelatine and bromide solution in small quantities at a time, thoroughly shaking or stirring

after each addition. This and all subsequent operations should, of course, be performed in the dark room.

We have now silver bromide in a fine state of division suspended in a solution of gelatine. We have also the other product of the double decomposition, nitrate of potash, and the slight excess of bromide of potassium. If finished in its present state this emulsion would be found to be very slow, not more sensitive than an ordinary wet plate, but by further treatment its sensitiveness can be marvellously increased. We will, however, leave the question of sensitiveness for the time, and complete this emulsion. In the previous experiment we got rid of the superfluous nitrate salt by the very simple method of washing the bromide of silver in several changes of water. We have now entirely different conditions to deal with. The silver bromide, instead of falling to the bottom of the vessel, is held in suspension. However, by taking advantage of that curious property of the solid colloidal bodies of allowing crystalloids, when in solution, to pass through them, that is to say, by the process known as dialysis, we have an almost equally simple means of attaining the same end. All that is necessary is to allow the emulsion to set, and then to soak it for a sufficient time in water. As a matter of convenience and a saving of time, it is usual to separate the set emulsion into fine threads, or divide it into small particles. Another method, which is extremely useful under some circumstances, is based upon the affinity of alcohol for water. The fluid emulsion is poured into a quantity of methylated spirits, which abstracts from it the water, together with the soluble salts, the gelatine and bromide of silver being precipitated. In this case, of course, as the emulsion is left practically without water, a sufficient quantity must be added before remelting.

The emulsion being washed, is remelted and filtered. It is then ready for coating plates. After remelting, additions are sometimes made, such as a small quantity of alcohol, which causes the emulsion to flow more freely, antiseptics to enable it to be kept without decomposing, or chrome alum to prevent any tendency to frilling; but these are matters of detail which do not come within our present province.

We have now to take into consideration some of the conditions which govern the sensitiveness of emulsions, and here we are entering a region where conjectures are more plentiful than established facts. It is still a matter of controversy whether under any circumstances there is a chemical combination between the gelatine and the silver, or whether the gelatine acts simply mechanically in holding the silver haloid in suspension. We need not, however, enter into this matter here. We know that sensitiveness is dependent—to a very great extent, indeed, if not wholly dependent—upon the molecular condition of the silver. We know that this molecular condition may be altered or modified by various methods of treatment, and we also know that the extent to which the condition of the molecules can be modified is dependent upon their condition at formation. In the emulsion I have made the molecules of silver bromide are arranged in very fine particles. This we can determine by the colour of the light transmitted through a film of it being ruby or orange. We can, however, in several ways obtain a rearrangement of these molecules into particles of larger size, and it will be found within certain limitations that as the size of the particles is increased the sensitiveness of the emulsion is also increased. Every variation may be traced by observing the colour of the light transmitted through a film of the emulsion, it appearing ruby, orange, purple, blue, or grey, as the particles increase in size. The colour by reflected light being affected to some, but far less, extent. [The lecturer demonstrated this change in colour by passing round plates coated with emulsion at the various stages.]

The earliest method of treating a gelatine emulsion to increase its sensitiveness was that published in 1878 by Mr. C. Bennett. Having made an emulsion in a manner similar to that just shown Mr. Bennett kept it fluid and warm for several days by means of a water bath at a temperature of 90° Fahr. He found that the sensitiveness increased under this treatment for about seven days, when the maximum was reached. This process, by which Mr. Bennett produced plates far exceeding in rapidity any that had previously been produced, was, however, a very tedious one, and we are indebted to Mr. W. B. Bolton for having, shortly afterwards, published a method by which similar results are obtained in a much more direct manner. Mr. Bolton made his emulsion with a portion only of the gelatine, and boiled it, the bulk of the gelatine being subsequently added. He thus obtained, within an hour at the most, the same result that with Mr. Bennett's method required several days. There was also in this process the advantage that the greater portion of the gelatine had been subjected to the least possible destructive influence: for there is no doubt that either keeping gelatine in a liquid state or raising it to a high temperature will result in a portion of it becoming decomposed and the

setting power of the whole becoming impaired, thus inducing frilling in plates prepared from it.

The next important step was the discovery by Dr. Monckhoven that, by the addition of ammonia to the emulsion, the modification of the silver haloid was accomplished without the prolonged digestion requisite in Mr. Bennett's process, or the high temperature in that of Mr. Bolton. Dr. Eder subsequently published a process based upon this action of ammonia, in which the silver nitrate is converted into ammonio-nitrate of silver before adding it to the other constituents of the emulsion. This is accomplished by the addition of strong ammonia, drop by drop, to the solution of nitrate of silver, until the brown precipitate first formed is redissolved. Emulsion made by this process is fairly sensitive without further treatment, and a greatly increased sensitiveness is obtained by a short digestion at a comparatively low temperature.

Such is a brief outline of the principal processes in gelatine emulsion making, from which modern practice differs only in matters of detail. It must not, however, be supposed that in emulsion making matters of detail are unimportant. So many requirements are to be provided for, and so many difficulties to be overcome, that it is only by strict attention to every detail that success is likely to be attained; and it must be borne in mind that in gelatine we are dealing with a substance of such unstable nature, that changes occur in it from the moment it is made into solution until it is again dried, and that heat, acids, and alkalis are all active agents in altering both its chemical and mechanical properties.

In collodion emulsions we have conditions which are in some respects the same as in gelatine emulsions though differing materially in others.

Collodion is a solution of pyroxyline in a mixture of ether and alcohol. Pyroxyline is prepared from cellulose, cotton wool being generally used, heated with nitric and sulphuric acids, by which treatment the cellulose becomes chemically altered, though not much changed in appearance. It is insoluble in water, and the most suitable kinds for emulsions are insoluble in ether or alcohol but soluble in a mixture of the two, and it is important to note that the amount of water contained in the solvents has considerable influence on the properties of the resultant collodion, more especially as to its mechanical behaviour. It is probable that no chemical combination ever takes place between pyroxyline, ether, or alcohol, and any of the other substances employed in the formation of an emulsion, except that some samples of pyroxyline may contain other organic matter as an impurity, and which may form an organic silver compound. The function of collodion may therefore more distinctly be laid down to be a mechanical one than in the case of gelatine.

Like gelatine, pyroxyline is not an uniform substance, and collodion made from different samples may differ widely in physical properties, the strength of the acids employed in its production, and the temperature during its manufacture greatly influencing the result. As the process of making it is attended by considerable risk and is very uncertain, even in experienced hands, it is not recommended that any attempt be made at its home preparation, but that it be purchased; and as the great secret of succeeding in collodion emulsion work appears to be in using a suitable sample of pyroxyline—for with some samples no amount of care seems to ensure success, while with others it seems equally impossible to fail—it is well, when a suitable kind is met with, to lay in a stock for future use.

Collodion emulsions may be divided, broadly, into two classes, washed and unwashed. These differ substantially in the fact that in the one case the emulsion is applied to the plates before the soluble salts produced in the emulsification are removed, they being removed by washing the coated plate itself, and in the other case the emulsion being freed from them in a similar manner to that employed in gelatine emulsions, the setting of the emulsion for this purpose being brought about by the evaporation of the solvents of the collodion.

While treating of gelatine emulsion some stress was laid upon the importance of the formation of the silver haloid in a fine state of division. With collodion emulsion this is still more important. With gelatine, however, there is, as has been shown, a considerable power of modifying the condition of the silver; with collodion this power is confined within very narrow limits. Gelatine and collodion emulsions differ from one another essentially in the fact that in the one the fluid medium is water, in which the silver haloids are to some extent soluble, and in the other the fluid is ether and alcohol, in neither of which are the silver haloids soluble. It is true that in some cases water is also present, but this must necessarily be a small portion of the whole or the pyroxyline would not remain in complete solution.

Taking the existing conditions into consideration, it will not be difficult to conceive that a far more complete contact can exist between the particles or perhaps the molecules of gelatine and those of the silver

haloid than can exist between those of collodion and the silver haloid, and as it is probable that one cause at least of sensitiveness in a gelatine emulsion is due to this intimate connection between the silver and gelatine brought about by the solution and redeposition of some portion of the silver, the fact that collodion emulsion cannot be made as rapid as gelatine may possibly thus be accounted for. There is, however, in applying this theory to collodion, the fact to be taken into consideration that those who have succeeded in making the most rapid collodion emulsions have generally insisted on the importance of using bromides which are soluble in alcohol, and dissolving the silver nitrate also in alcohol, thus avoiding altogether the presence of water. The conditions are also different in respect that in rapid collodion emulsions an excess of silver nitrate is usually used.

As an example of a collodion emulsion I will take the formula of Mr. John Nesbit, by which an emulsion is produced in the simplest possible way, having no pretensions to rapidity, even as a collodion emulsion, but suitable for any purpose for which rapidity is not required, such as making lantern transparencies.

FORMULA.

Pyroxyline.....	60 grains.
Ether	2½ ounces.
Methylated alcohol	2½ „
Bromide of ammonium ..	63 grains (53 and 5 excess).
Water	about 100 minims.
Methylated alcohol	1 ounce.
Nitrate of silver	100 grains.
Water	60 minims.
Nitric acid	1 drop.

The bromising solution should be first added to the plain collodion and then the silver solution introduced a little at a time, shaking between each addition.

In this state the emulsion should be set aside for twelve to twenty-four hours to ripen, at the end of which time it is to be poured out into a dish and the solvents of the collodion allowed to evaporate until it is sufficiently set to handle. The pellicle is then washed in a similar way to that employed in the case of gelatine, until the soluble salts are removed. When this has been accomplished the pellicle should be squeezed in a piece of calico to get rid of as much water as possible, and then dried, either spontaneously or by gentle heat, an alternative method being to soak the pellicle for some hours in strong methylated alcohol changed a few times. For use, the quantity of pellicle obtained by using these quantities of material should be dissolved in about eight ounces of a mixture of equal parts of good methylated alcohol and ether 725.

In this emulsion there are five grains of bromide in excess of the combining equivalent, and there is also a comparatively large quantity of water introduced, which would not be permissible if the emulsion were to be used as an unwashed emulsion, but as it is afterwards removed it is of no consequence.

I will now bring my paper to a conclusion. I have, perhaps, not even touched upon many points which might claim to be included in the A B C, but it is not easy to define the exact boundaries of the subject. A large number of those before me will have found nothing to add to their previous knowledge, but I trust there are also some to whom much that I have said is new, and that they will have learnt something at least of the general principles involved in photographic emulsions.

ALEXANDER MACKIE.

CONTINENTAL PHOTOGRAPHY.

[Translations and Abridgments.]

VISIT OF MESSRS. EDER AND STEINHEIL TO PARIS.

PROFESSOR EDER and M. Steinheil took part in the Astronomical Congress in Paris, at which they were the delegates of their respective Governments. The visit was a short one, but the Parisian photographers did their best to organize means to make their visit a pleasant one, a highly representative committee of all branches of the art-science having been formed to bid them welcome. At a dinner they were informed that their labours were well appreciated in France, and during their visit leading photographers like Messrs. Quinsac, Lemerrier, Bonssod, Valadon & Co., Nadar, and Liébert, gave them full facilities for the examination of their establishments. The Salpêtrière was visited by Dr. Eder, in company with M. Weiss, director of the Observatory at Vienna. Dr. Charcot received them, and the photographic works of M. Londe particularly arrested their attention. They expressed their regret that Austria had not a photographic laboratory of the same kind annexed to an analogous hospital. They examined a multitude of photographs of interesting pathological

cases which amply demonstrated the useful nature of the proofs, taken often under such circumstances of movement that instantaneous exposures alone could be employed to accurately record the facts, and to afterwards afford facilities for studying interesting symptoms.—*Le Moniteur de la Photographie*.

PHOTOGRAPHY AT THE ASTRONOMICAL CONGRESS.

Among eminent photographers present at this Congress were Messrs. Janssen and Prosper Henry, of France; Common, of England; Lohse, of Germany; Hasselberg, of Russia; Gill, of Capetown; and Dunet, of Sweden. The Congress appointed a permanent committee to go into points of detail, but the dimensions and focal length of the objective to be used in each case have been settled: the diameter will be thirty-three centimetres and the focus three metres forty. Ordinary dry plates will be employed, not necessarily of any particular brand, and a suggestion made by Dr. Eder, and others, that other photographs should be taken also upon other plates, has been referred to the permanent committee. M. Hasselberg produced prints proving that views taken of the same portions of the heavens by an orthochromatic plate and by an ordinary plate presented essential differences. The purely photographic side of the questions considered was dealt with almost alone by Dr. Eder. M. Paul Nadar photographed a group of all the members of the Congress, and an hour after the exposures were made proofs were circulated in the hall of the Congress, to the astonishment of the astronomers. The prints were upon Eastman's positive paper. It is believed that the work decided by this Congress will not begin in less than two years from this time, and that it will take fifteen years to complete.—*Le Moniteur de la Photographie*.

PHOTOGRAPHY AT THE UNIVERSAL EXHIBITION AT PARIS.

At the Universal Exhibition in Paris in 1889, photography, Class XII., will be allotted twice the space it had at the Paris Exhibition of 1878; then it had 435 square metres; in 1889 it will have 962 square metres; the position will have a northern aspect, and portions of it can easily be utilised for the exhibition of transparencies. A special section relating to the history of photography will provide facilities for the display of historical documents, and without any expense to the exhibitor. All applications for space should be addressed to the General Director: such applications in the first instance involve no charge and no obligation; it suffices to express a desire to exhibit, and to state what space is wanted for the purpose.—*Le Moniteur de la Photographie*.

MISCELLANEOUS ITEMS.

It is often difficult to make paper adhere to metals. M. Eliel gives the following formula for a mixture which can be used for metal, glass, or wood:—gum tragacanth, 30 grammes; acacia gum, 120 grammes; water, 500 c.c. Dissolve, filter, and add 2½ grammes of thymol suspended in 120 c.c. of glycerine; then add enough water to make up the bulk to 1 litre. This bath will keep a long time.—*Revue Photographique*.

At its meeting on March 8 the Syndical Chamber drew up the proposed rules in relation to photography at the Paris Universal Exhibition of 1889. The proposals have to be submitted to the approval of the administration.—*Revue Photographique*.

M. Gawalowski publishes a simple means of preventing salts from crystallising on the sides of the upper parts of filters; he impregnates the desired parts of the sides of filters with paraffine, wax, or any suitable fatty body.—*Bulletin de la Société Française*.

To restore negatives which have been intensified with mercury and afterwards turned yellow, remove the varnish by means of alcohol, put the plate in water for a short time, then in the open air, because of the bad smell, apply sulphide of ammonium. The negative will assume its original appearance, then wash it in a great quantity of water.—*Deutsche Photographen-Zeitung*.

THE RIVAL PHOTOGRAPHERS.*

F'en about half an hour Mr. A. kept the old gentleman and his pretty daughter in the studio, and no doubt secured as good negatives as any photographer could from such subjects. The old gentleman was evidently well-to-do, and one not to be permitted to leave a photographic studio too suddenly. It is a very peculiar feature in photography—although not altogether confined to that profession—that the operator more especially if he be the proprietor or holds his place on salary and commission, seldom fails to find out the monetary condition of his sitter. I may also say that not a small amount of the consideration—I won't say flattery—that he receives at the hands of the photographer may be placed to the credit of his banking account.

* Continued from page 276.

It may seem almost incredible, but I can vouch for the fact, that you can find photographers who, should one of their customers unexpectedly pull out a cheque-book to pay their account, will insist on taking them all over the place, and explaining the various merits of every specimen in their show rooms. I need hardly say here that no such customer should be allowed to live another month without at least one family portrait in oils, to hand down to posterity the image of one so deserving of undying memory in the annals of their family. I have seen many a glorious, although bloodless, struggle carried on under these conditions. On the one side, the high-minded photographer, full of sympathy, depicting the inevitable sorrow of all that must be most dear to his customer at not having a lasting portrait of "Dear Uncle Benjamin!" And I must say I agree with him, notwithstanding that I benefit occasionally by his eloquence. On the other hand, I have seen the victim—I mean the worthy patron of art, photographic art—several times during the struggle put his hand to his pocket and take it away again. I have often thought, in the solitude of my chamber, whether it was to get his pocket-handkerchief to wipe away the evidence of his emotion, or to recompense the fervour of the photographer by pulling out his cheque-book, and acknowledging his defeat.

Evidently Mr. A. had formed the idea that the old gentleman and his daughter were worthy of no mean amount of attention, for having *waved* them (if I may be permitted the expression) back into the dressing room to resume their belongings, he bravely, but determinately, awaited their reappearance. He had not long to wait; a couple of moments, and they were (so they thought at least) ready to depart.

"I suppose we had better pay now?" said the old gentleman.

"It is the usual custom to pay at time of sitting; but in such a case as yours there is no absolute necessity."

"Oh, business is business! As it is your rule, I do not wish to be an exception."

"Since you insist," resignedly.

Of course Mr. A. was very grieved that such a decision should have been arrived at; but, like a sensible man, would not let his feelings get the better of him. However, he made his mind up that he would be revenged, and determined to follow this positive *cash* customer, if necessary, down every step of the stairs, and even finish the struggle on the doormat, rather than he should leave his studio without deciding to bestow an oil-painting upon his longing relatives.

"Now, my dear, I think we had better go. Mr. A.'s time must be very valuable, and we have already occupied too much of it."

"Not at all," breaks in Mr. A. "From the observations you made, I am convinced you are possessed of considerable knowledge in artistic matters. You expressed the desire to have a true likeness, none of those distorted and untruthful pictures produced by tampering with a pure and simple art."

"I have always argued, if I have a *likeness*, it must be *like* me. One my friends can recognise at a glance."

"Such an one as photography in its own truthfulness can produce?"

"Precisely."

The old gentleman really thought he began to know something about it, and, indeed, began to give his opinions very freely on pictures of his friends that had been so altered in some way or other, he knew not how, that he could not without very great trouble tell who they were. In showing him round the show room Mr. A. drew his attention to some truly excellent pictures, ones in which he might feel justly proud. Unfortunately, we forget at times that we only make specimens of successful subjects, and not the ordinary run of sitters. If Mr. A. would make his mind up to fill his cases with the portraits of the first twenty-five sitters that entered his studio, I fear he would have had a very different set of pictures to set before the eyes of his customers.

"These pictures, you may observe, possess all the softness and character of life. I have set my face entirely against the trickeries and humbug introduced by so many photographers of the present day, and flatly refuse to accept their pernicious help. If truth is what we want, the plain photograph must be truth. Defects, if they were not there in nature, could not be produced by the lens and thrown on to the plate. I positively grieve when I see a good, a really superior photograph, ruined by the uncultured and reckless 'pencil pushing' of that parasite of photography—the retoucher."

The old gentleman looked fairly bewildered at the vehemence with which he assailed something of which he knew nothing. As for myself, I was still more bewildered than he was, when I saw that Mr. A. really believed in all that he was saying. There is no one more ready than I am to acknowledge the ruin caused to a good negative by bad or injudicious retouching; but I will stoutly maintain that, by clever and capable retouching, even the *best* negative (por-

trait) can be improved. It is not the amount of work in such a case that would make the difference, but the judgment shown in placing what little might be requisite to secure perfection.

I am willing to prove what I state by taking the best *portrait* negative, even of a subject in every way favourable to photographic exigencies, and I will guarantee to improve it by retouching. As to whether I do *much* or *little*, that is *my* business; but I will *improve* it.

If the production of a really good photograph be the greatest point of excellence attainable in photography, I at once say—Eschew retouching most certainly. But if the production of a pleasing and successful *portrait* be the highest attainable object, I hold the matter is quite different. I will even go further. I will leave out the necessity of a portrait being *pleasing*, and, of course, thereby successful, and merely ask for a *true* portrait; and this, I say, photography will not produce with certainty unaided. It is in such cases, and they are many, that retouching is essential. Many are the cases, too, in which "pencil pushing" is absolutely indispensable. Of course, I speak of skilled retouching.

If the photographers who have such a contemptuous opinion of retouching would not employ unskilled labour (because it is cheap), they would not have so many grievances against a branch of photography that not one per cent. of their number dare ignore in their everyday business. I regret to have to say it, but the *general* tone of retouching is going down, and that only owing to the number of inefficient people who can obtain work from even good photographers at a very low price. It is the *low price* that does it, and the photographers shift the blame off their own shoulders to those of the poor retoucher. There are *really good men* leaving this branch of photography every season, as the price has descended to such a degree that they can no longer make a respectable living at it.

While I have been saying a word or two in favour of the poor retoucher, Mr. A. has been hammering away at him, and to some effect, but in a less complimentary manner.

"Well, I must say I see a great deal of reason in what you say, and hope you will turn out such pictures of myself and daughter as will give us every satisfaction, and be recognisable by our friends at a glance."

"Believe me, no pains will be spared. Excuse me half a moment."

Saying this he went to a speaking tube, and asked his assistant if he had developed the negatives, and if they were good. He received an answer in the affirmative. They were good in every way, so returning to our friends he said, "I have just asked my assistant how the negatives have turned out, and he says they are all right. I can therefore promise you that you will be satisfied. I will let you have the proofs in about a week from now."

"Do, please, I am anxious to have them soon."

"Can I not induce you to decide upon a life-size portrait in oils?"

"I certainly feel disposed that way, but will not decide to-day."

"Your daughter would make a most charming picture."

"You think so? Well, to tell the truth, I feel more disposed to have a picture done of her than of myself."

"Why not have both?" insinuated Mr. A., as if he had been a business man all his life.

"Well, if I do that I would have to have her mother done too. No, I think if I have any done it will be my child's."

"Shall I book it?"

They were not yet on the doormat, but the old gentleman was gradually failing in strength of mind. However, as he got towards the threshold he rallied, and with a supreme effort said, "You have been very kind to us and taken a lot of trouble. I really want a portrait of my daughter, and I tell you what I will do. You may book her portrait, but I won't give more than twenty-five guineas. I only make one condition."

"I accept your offer. And the condition?"

"That the photographs in the first instance give us satisfaction, as it will be from one of them the portrait will be painted."

"Then I will book your order without hesitation, as I cannot possibly fail. All that *photography* can do to make your pictures perfect will be done. In a week from to-day you will have the proofs. You will only have to let me know which you prefer, and the portrait will be begun at once. I will just take the necessary notes regarding colouring. The dress will be according to your own fancy."

Mr. A. here proceeded in the usual way to make notes regarding the colouring, and having completed same, thanked our friend (I say *our* friend advisedly, because *any one* patronising us is a *friend*), escorted him to the inevitable doormat, and, with a final word of thanks, wished him "Good day."

Getting back he booked order, saw after plates, which were satisfactory, told his assistant to have them printed earliest possible moment, and have proofs sent home.

"Don't you think, sir, as there is a painting order hanging to it, you had better have them retouched?"

"Retouched!!!"

"Yes, sir. They are very freckled, especially the lady's one."

"You always bother me about retouching, and I always tell you I will not have it. It is *not* photography. If you develop them properly, and secure a proper density, the freckles will not show unduly. Photography, in its infinite resources, has provided for all these little difficulties, and by its aid must I make the pictures successful. But never, never, my boy, by the aid of a retoucher."

There was nothing further to do, then, than develop, intensify, dry, varnish, print, tone, mount, roll, spot, and send home the proofs. Proofs of what could be done by photography *without* the aid of retouching.

REDMOND BARRETT.

(To be concluded in our next.)

PHOTO-THERMOGRAPHY.

WE have received the following communication, together with two pictures on glass, from Mr. George Mason, of Glasgow:—

"I send you on to-night a transparency of one of the most wonderful things in the way of impressions I have ever seen. This picture, as you see it, is photographed from a piece of glass that covered an etching on which it must have imprinted itself from the etching behind. However, the etching and the glass in frame were never in contact, as there was an overmount between.

"The etching has been in the frame for some years, and has been hanging in a strong light. Messrs. Lawrie & Son, the fine art dealers here, sold the etching, and on removing it from the frame found the front glass had a faint impression of the picture on it, which we have photographed to send to you; from the transparency enclosed you will see the result. Of course the exposures turn out positives, the glass being negative in impression. The frame was three feet seven inches by three feet. The picture was one foot eleven inches, and one foot three inches the subject *The Pied Piper of Hamelin*. A mount fitted between the picture and the glass.

"Now this glass would be about a sixteenth of an inch away from the etching and in front of it. Have you any idea how the impression could be taken up? It must have been thrown back from the picture to the surface of the glass again. It is such a curious thing and probably new to you, that you might be able to make some use of it."

Having carefully examined these truly interesting photographs, we shall endeavour to give a few words of explanation concerning the phenomena.

There is a principle in physics first investigated by M. Ludwig Moser, who in 1842 announced the following fact:—"If a surface has been touched in any particular parts by any body, it acquires the property of precipitating all vapours which adhere to it, or which combine chemically with it on these spots, differently to what it does on the other untouched parts." This was the form in which the law was first announced, but further investigation showed that contact was not necessary, mere juxtaposition sufficing. Emanations were found to be given off from one body to another, in virtue of which vapours were condensed on certain parts in preference to others. Moser designated the phenomena as having been produced by "invisible light," but Hunt adopted the more philosophical term thermography, and made numerous and valuable investigations in this department of physical science, which he published in the *Philosophical Magazine* of the period, and elsewhere. Having found that a blackened paper gave more forcible radiations than a white one, he tried the copying of printed matter, and eventually succeeded in doing so, developing the image by various agencies. The specimens received from Mr. Mason possess an exceptional degree of interest, and are by far the best examples we have seen. That their existence is attributable to thermography, however unhappily it may be named as applicable to this case, we have no doubt. It will afford us pleasure to exhibit them to any who are interested in this still little understood department of physics.

THE FASCINATIONS OF PHOTOGRAPHY.

[A Communication to the North Staffordshire Amateur Photographic Association.]

PHOTOGRAPHY as an intellectual pursuit is so full of *pleasurable* fascination, that few, if any, who have once commenced its practice care to relinquish it again. The delicate chemical manipulations and the wonderful effects evolved by their means, hold us enthralled, as it were, from the time of developing our first negative—and how beautiful we thought it!—to the time when we make our own emulsion for the

plates, or soar to the higher branches of this beautiful art-science. Apart from this, it is a pursuit which can be followed by the tired man of business, or the man of leisure, and even the fairer sex may partake of its pleasures, as the *rudiments* are soon learnt and the chemical operations few and easy.

Sets of apparatus can now be bought for fifty shillings, or even less, so that it is within the reach of nearly all. To all, however, who can afford to do so, I would advise the purchase of a really good set, of a size not less than half-plate, and fitted with rectilinear lens and six double dry slides.

Thus equipped, one has only to wait for King Sol, and throwing care to the winds, may sally forth in search of good "shots" or "bits" for his camera. Here we come across an exquisite bit of woodland scenery, such as is seldom seen except in England—it is quite an idyllic fairy glen, at one end of which a cascade of sunlight glistened water is rushing and tumbling down the rocks into the rippling stream below. Everything is opportune for our success in taking a view of this "gem" of nature, and with our extra rapid plates and drop shutter we secure that which would take a painter weeks of application to achieve, and even then it would not be rendered in such truthful detail, as to do so, the beautiful, yet transient, effects of light and shade on the glistening water must be limned instantaneously.

Or, again, it may be that we are one of a merry picnic party, taking place, we will say, in the vicinity of the old moss-covered ruins of some interesting castle. What is likely to give us more pleasure in years to come than a photograph of the place and people present on the occasion? How many pleasing memories a glimpse of it recalls! These are only a few of the outdoor fascinations of photography, but others meet us at every turn. When after "grinding" hard in the office, factory, or shop, we take our usual annual holiday, what additional zest it adds to it when we are able to bring home with us mementoes in the shape of views of the places or things of interest which may be in the neighbourhood in which we are staying. Instead of sitting in our "apartments" smoking or reading, or "doing" the promenade in a listless fashion, we have an incentive to get out in the fresh air in search of pastures new for our camera; and while gaining health and dispelling *ennui* thereby, the higher faculties of our mind are agreeably brought into play in choosing the most artistic point of view, judging the actinic power of the prevailing light, and requisite time of exposure.

To the cyclist photography lends an additional charm, as in his ramblings many and oft will some enchanting picture present itself to his view, which can be readily transferred to his dry plate, and developed at his leisure.

To the manufacturer the camera offers a ready and accurate means of taking photographs of his patterns or wares, while to the naturalist or antiquarian its aid is invaluable. The naturalist is able to secure instantaneous representations of any part of the body while in motion, and the antiquarian to obtain correct pictures of ancient monuments or buildings, which, in the ordinary course of mundane affairs, must either fall a victim to the ravages of time or the spirit of Vandalism.

W. E. LECK.

(To be continued.)

WHERE I WENT WITH THE CAMERA.

NO. VI.—BERLIN.

FROM Arnheim I booked right through to Berlin, a weary journey of some twelve hours or more. The refreshment arrangements on the various lines, however, are conducted in such an able manner that they tend to alleviate considerably the tediousness of such a long railway journey. Our railway companies at home might take a lesson from the way a dinner is served up on these lines. You are asked at Oberhausen if you wish to dine; if your answer is in the affirmative the guard sticks a little ticket on the side window of your compartment, a ticket for each person if more than one. When you come to the next stoppage a neat little tray is handed in to you; from the little tickets the waiters know at once where to deliver these. The tray is so constructed that it rests upon your knees without inconveniencing any other passenger. The neat arrangement of this tray was a perfect picture. A small metal basin with soup, two electro-plate covered dishes with different kinds of meat, another compartment with stewed fruits, a triangle of silvered wire in the centre into which is fixed the bread, pepper, salt, table napkin, &c., all combining to make the handiest of dining tables and pleasantest of dimmers. At the next stoppage the trays are removed, and the money collected—in this case, two and sixpence. Coffee, milk, beer, and fruit, are offered for sale up and down the platform at almost every station on the line, so that one has every chance of being comfortable from a gastronomic point of view.

One has not the opportunity of getting more than a very hazy idea of

the surrounding country, looking at it from the window of a railway train as it speeds along. On this journey I was impressed with a general tone of flatness all over, relieved now and then by a picturesque little bit, but on the whole uninteresting; very likely it would improve on a closer acquaintance. What was more perceptible to me was the gradual alteration of feature, form, and little touches of manner, observable in the changing nationalities, represented by the platform loungers, as we stayed at the various stations on the way.

Berlin is a noble city—a city of princes and palaces; a city of beautiful buildings and magnificent streets, of gorgeous monuments and graceful statues, of expansive parks, blooming gardens, and charming pleasure grounds; a city of splendour everywhere. Most of the pictures I got when in this city, however, were taken from windows, as there is a very general feeling abroad against photographing in the streets. I asked some friends why this was so; the only reason I could get from them was, that you were likely to create a crowd in the street, and the authorities would not have that. This might have been a feeling more than a fact, but all the time I was there I did not see any attempt to photograph openly anywhere. As there was no chance of being interfered with when making exposures from private standpoints, the pictures I got were made from these.

When in Berlin I visited an exhibition of modern paintings, colossal in dimensions, and the quality of work exhibited fine beyond description. This Exhibition Palace was built as a centenary celebration in commemoration of Frederick the Great. Pictures by the greatest modern masters, collected from all parts of the world, were here exhibited. There were thirty rooms filled with them. It would have taken a couple of days to walk round and take even a cursory glance at the various classes of work exhibited, and to have made a careful examination of all the pictures it would have taken weeks. There was some talk about having the building retained as a permanent Fine Art Gallery, and if it still stands it is well worth seeing, the dome above the entrance-way alone being a perfect masterpiece of artistic decoration.

As a rule, all the people here dine out; what we call the comforts of a house are not indulged in. They leave their dwelling-houses and fill up their leisure time in the restaurant, the café, the concert-room, or the theatre. After they have made their round of pleasure, home they go to sleep. About two o'clock in the afternoon the restaurants are at their busiest and gayest; the many tables crowded with ladies and gentlemen, forming little social gatherings, enjoying themselves to the full of their bent. The "Four Seasons" and the "Dressel" were the best appointed restaurants I visited when in Berlin. The Germans have many dishes peculiarly their own, which are first-rate, and they will go on with course after course for a couple of hours, if you will let them supply and are open to pay. Between ten and twelve o'clock at night the cafés are crowded with visitors of all classes eager to take the last little pleasure out of the day.

To judge from the number and quality of the portraits of the Royal Family to be seen hanging in all places of entertainment, from the first-class restaurant to the commonest café, the Berliners must be the most loyal people on the face of the earth. The King, the Crown Prince, and also Prince Bismarck—life-sized pictures of them on every wall, beautifully finished oil paintings, and fitted into gilt frames that alone must have cost many pounds apiece. How fond they must be of their rulers!

I went to the theatre. It was not tedious, for the whole performance did not take more than two hours and a half. We went in about seven and came out about half-past nine o'clock. I saw a ballet that had been running for some time—a great success—"Amour" I think they called it. The plot was very extraordinary—it began with Adam and Eve in the Garden of Eden, and wound up with some of the latest Prussian victories. The performance was short compared with what we get at home, but the house was crammed, and the audience seemed perfectly satisfied.

When in Berlin I visited the mount manufactory of Carl Ernst & Co., which is one of the largest factories of photographic mounts, as a special business, in Europe. The manufactory consists of a building five storeys high, the square of it being in proportion to its height. On entering the office of the works the first thing that meets the eye of the visitor is the following notice, framed and hung up on the wall opposite the doorway:—

"Say what you want,
Short and decided;
Leave off all superfluous phrases;
Who needlessly uses them wastes our time.
He steals from us—and
'Thou shalt not steal.'"

This means business.

The partners of the firm treated me with the most extreme courtesy and kindness, and placed their time pretty much at my disposal. They showed me over all the works, and explained with considerable detail the various points of interest in the making of mounts—beginning at the plain boards and going right on to the finished article in all its forms. Every flat teemed with hands all busy at some portion of the work. On the first floor they were making ferrotype envelopes; after the printing of these they are cut out, one by one, by a large machine that takes two hands to work. The amount of labour necessary to produce a thousand of these positive picture holders which are sold in the open market at

twelve shillings for that quantity seems incredible. They are first printed, then each one is cut out singly by the machine, after that mounted with the pink paper backing that forms the picture slip, then packed, boxed, and sent into the market to be sold at that small sum.

As we ascend we come to the department where they are making cut-out mounts, with gilt bevel edges round the opening overmounts for photographs. The next is the printing department, where all the lithographic work is done by steam power. The *carte* and cabinet mounts are reprinted in sheet, and afterwards cut to the size. The ordinary mounts used by photographers—and generally printed on both sides—are all cut by hand, girls sitting all round punching these mounts out of the printed sheets one at a time, and producing hundreds of thousands per day. They have not been able to get a machine to do this kind of work yet, but a girl will cut out seven or eight thousand *cartes*, or five thousand cabinets, a-day; so that it can be easily understood that with a lot of young hands employed a considerable quantity of work could be got through.

The bevelled edged mounts are cut by machinery. The boards are cut into strips first, then the size of card is got by passing the strips through the machine crossways, the knives being arranged to cut them exactly to the proper size.

The bevelling and gilding of these mounts are hand done. Some fifty of them are taken and clamped between two boards placed on a stand, and the workman then scrapes or planes the edge to the bevel required, when they are handed to the gilder to finish. These mounts are usually stamped with the photographer's name and address afterwards, in gold leaf, and singly. In the lithographic department where the designs were made up, it was very interesting to see how they pieced together little bits of transfers taken from different existing designs, the combination forming quite a new pattern with only the photographer's name and address original in the whole composition, by this method saving all the time of drawing and rewriting the whole design anew.

On going over works like this devoted to the production of one class of goods only used in the photographic trade, one cannot but marvel at the growth of the art-science as a business, and ask, if so many hands are employed here, how many hundreds of thousands, scattered over the world, must be employed in the various branches necessary to photographic picture making as an industry? MARK OUTE.

BALLOON EXPERIENCES OF A TIMID PHOTOGRAPHER.*

MY SECOND ASCENSION.

As we were compelled to wait until five p.m. before beginning our ascension on September 2, I had very little confidence of success in my attempt at photographing; and the results obtained proved that there was reason for my apprehensions. At that time of year the light is very weak, so that the taking of instantaneous views is difficult, even under the most favourable conditions. When we remember that in addition to this the light also grows rapidly weaker as the sun approaches the west, it is easy to understand that the conditions were very unfavourable to balloon photography.

When the result was known, Mr. Moore offered to make another ascension solely for the purpose of photographing. As my first ascension had quite overcome my fears, and had left me with an earnest desire to again experience the pleasures of an aerial voyage, I gladly agreed. My first ascension enabled me fully to understand what I had suspected before, that it was a much more difficult matter to get instantaneous views from a balloon than from some more secure support. After much time spent in altering apparatus, constructing some new parts, and in further experiments, it was decided to make an ascension on October 16, if the weather should be favourable.

The day was all that we could wish, with the exception of considerable haze in the atmosphere; the wind was very gentle, blowing from the south-west, and high in air we could see by the motion of the clouds that there was an upper current, also moving slowly, toward the south-east. As the inflation progressed, and it was evident that we might soon be off, I found it impossible to ignore a rapid increase of nervousness on the prospect. Those who have made many ascensions assure me that this dread felt at the moment of starting is rarely outgrown by any amount of experience. We went up much more slowly than before, and were for some time within hearing distance of our friends. This was because our ascensional force was more nearly balanced by the greater weight of sand carried.

We were soon over the hills east of Winsted, and before turning from it exposed one plate on a part of the town on which the illumination seemed particularly favourable, and which fortunately proves to be one of our best views. This photograph, taken just as we attained an altitude of 3050 feet, although not so perfectly sharp as some of the others, is nevertheless one of our best, owing to its fine gradation of light and shade, and to the superior delicacy of chemical effect in the negative. The portion of Winsted included in the view is at the northern end of the borough, and at the lowest point within its limits reached by the stream which supplies power to the factories closely set along its banks. Part of our main street passes through the centre of the view,

* Concluded from page 293.

and some other streets are included, mostly occupied by dwellings. Within the limits of the picture are three of the many factories whose business forms the chief support of the place. Many of the garden plots near dwelling houses are plainly shown; also the woods on a steep hill-side at the further side of the view. The shadow from a passing cloud darkens one corner of the picture, blotting out all definition in that part, and showing how useless it would be to try such work without a good light.

As some may be interested in the details of our photographic equipment, I will give a description of it. We used 5×8 plates, which size seems best suited to our purpose, as it allows a considerable extent of country to be included in the view, while the apparatus need not be unduly bulky or heavy. The camera was quite light, as all the apparatus used in a balloon must be, but not so fragile as to sacrifice rigidity in keeping the distance at which the plate is set from the lens, as this is of even more importance than lightness. The plates used, which must be of the utmost sensitiveness, were contained in the necessary number of dry plate holders, which in turn were carried in two boxes made to pack them securely. In any future ascensions these boxes will be provided with locks, as we have learned to our cost that nothing will so excite the curiosity of the average hotel porter as a photographic apparatus left in his care. The object of packing our plate holders in boxes was twofold: first, the plates were better protected from light and more convenient to carry, as in ordinary work; second, as we knew that the landing is not always as orderly as could be wished, we hoped, by keeping hold of our holders at such a time, to save our exposed plates, at least, from injury.

A "finder" was attached to one side of the camera, to enable the operator to see just what would be included in the view at the moment of exposure. This instrument is like a smaller camera, except that no provision is made for focussing, and the ground-glass is permanently fixed at the proper distance from the lens. The ground-glass of the finder was of the same proportion as the larger plates on which the views were secured, and had lines drawn from either side, crossing at right angles in the centre. The finder is attached to the camera in such a position that any object appearing on its screen will be sure to occupy the same position on the dry plate.

The lens used was of the rectilinear kind, especially made for groups and instantaneous work. The instantaneous shutter, used to cut off the light and give the plates their very brief exposure, was fastened in front of the lens, and was of the kind called an eclipse, but was considerably changed by me before our second attempt. The springs which caused the sudden motion, and admitted light to the camera for an instant, exerted a force of eleven pounds when the shutter was set for action, and were, of course, adjusted to give a quick rather than a forcible motion.

My manner of operating while in the balloon, when we had determined on "taking" any place we might be approaching, was, after deciding on the correct focus, first to "set" the shutter, then insert the plate holder and draw the slide; the camera was then taken in the left hand, with the rubber bulb of the "pneumatic release" of the shutter in the right. Then we must wait until the revolution of the balloon had brought the desired place opposite the camera, when it was pointed so that the view was in correct position on the screen of the finder, the rubber bulb was pressed, and the exposure was made; the slide was then inserted in the plate holder, the holder removed and boxed, and we were ready for another subject. At the same time Mr. Moore recorded the exposure for me, taking down the number of the plate holder, the subject, and the altitude as shown by the barometer. The record was a very necessary guide in developing the plates, and it was kept by Mr. Moore, because in our flight objects of interest were presented in rapid succession, and much time was saved by this division of labour; as it was, the camera was hardly out of my hands during the whole time of our ascension.

The revolution of the balloon referred to is a very curious phenomenon which was a source of much inconvenience; a free balloon revolves almost constantly, and with varying rapidity. The direction of its motion was in both instances of my observation "with the sun;" that is, the side of the balloon and car towards the south turned towards the west and its northern side towards the east.* Many times, just as I was about to expose a plate, one of the cords from car to hoop would come in the way and force me to wait for another open space.

The balloon continued to rise after we had secured the view of Winsted, and the wind carried us towards the north-east, when, at an altitude of 3750 feet, we were nearly south of Riverton, of which we caught a good view.

We continued rising, and soon Moore told me to look up; on doing so, I found the balloon was on the point of disappearing in a bank of cloud, which shut out the blue sky for some distance on each side of us. Under this bank of cloud, which appeared level and dark grey in colour, the light was much reduced, and the chill felt at its near approach produced a feeling of depression.

The balloon entered the cloud, being gradually cut off from our sight as the mist thickened: at length the cords passing up from our car seemed to melt away into the mist, leaving us "without a visible means of support." Soon we were in the midst of the cloud, and could feel the dampness; it seemed like moving through a thick fog.

* A high scientific authority says that the revolution of a balloon one way or the other is purely accidental, and depends on the unbalancing of the resistance of the balloon in the air on its different sides; the term *sides* being used in reference to the vertical drawn through the centre of gravity.—*Editor of The Century.*

As we emerged from the upper surface of the cloud, a most wonderful picture was presented to us. In the south a line of the same stratum of cloud we had just left stretched across the sky. This line was at such a distance that we could see both the upper and under sides at once, the dark lower side forming a fine contrast with the upper, glowing in the sunlight.

The sun's rays, streaming across the edge of the clouds, projected a series of long beams of light and shadow to the earth, as is sometimes seen at sunset. In the distance the eye caught a reflection of light from Bantam Lake at Litchfield and from Lake Waramaug farther west, while the many lakes of Winchester and New Hartford seemed directly beneath us. Our barometer told us that the clouds which formed so beautiful an object, and of which we secured a fine picture, were floating at a height of 5500 feet from the earth.

While sailing above a large extent of cloud, one's sense of isolation from the world is oppressive. My view from above the clouds was no disappointment. The appearance of the clouds, seen from above, has been compared by some to the ocean, and by others to an expanse of snow. It is all and more than this, for the continual change, clouds breaking up to form other masses, surging and rolling, with their wonderfully silent, steady, slow motion, impressed me with a deep sense of grandeur and awe.

While passing over a large detached cloud, it was our good fortune to observe a phenomenon rarely seen by man. We had been watching the shadow of the balloon as it slid along the ground, or as it was occasionally projected on an intervening cloud, being then surrounded by a brilliant circular rainbow. We were much surprised on passing over such a cloud to see the shadow as before, but with the addition of another balloon!

The second balloon-shadow was directly opposite the first or upright one, and inverted, so that one shadow of our car served both, while there were two perfect shadows of passengers, netting, and gas bag; the rainbow which inclosed the whole was at this time of exceptional brilliancy. We are entirely at a loss in attempting any explanation of the double balloon shadow; it is certain that we saw it, an object of wonderful brilliancy and distinctness, for about thirty seconds, while we passed over one large cloud; then it was gone, and we hardly hope to see it again.

In connection with this picture we met with a most vexatious piece of misfortune. I made an exposure on that shadow as we were passing quickly over it, and naturally wished most earnestly that I might develop the image successfully, but fate was against us; for in Hartford some one out of curiosity to see the picture, opened the plate holder, exposing the plate to gaslight, and the invisible spirit of my most valuable negative was gone beyond recall. As the subject was of so much interest scientifically as well as for its rarity, we had a drawing prepared from which our illustration is taken, and which is a correct representation of the phenomenon as we saw it.

After gaining a considerable altitude the gas, which does not at first entirely fill the balloon, expands by the diminished outside pressure of the rarefied air and quite fills the envelope; then the neck of the balloon hangs wide open, giving a fine view of the interior, which seems as though filled with air; for the gas is usually quite transparent. This view, the cords of the netting plainly outlined through the cloth, gave us a keen sense of the frailty of our support; there really seemed to be nothing to keep the whole affair from falling down upon us.

While passing over a brook in a rough piece of country, we decided to try the effect of a view directly down through the hole in the bottom of the car, which was left for that purpose; we had found it of little use, for the reason that the balloon so seldom passes directly over the most interesting objects. The hole had been left open, and was at first a source of considerable annoyance, as it took us a long while to overcome the impression that, as one or two towns might be seen through it, we were in danger of falling through ourselves.*

The picture obtained by looking directly down through this hole is one of the best for conveying an idea of the height from which it was taken—over six thousand feet. It should be examined from a considerable distance, and the effect of height will be better produced if the observer will look *directly down* upon it. Three waggon roads are included in the extent of the view, with several dwelling-houses and barns, some cultivated fields, and considerable pasture land and forest. The shadows cast by the trees, and by the irregularities in the land, give the picture some resemblance to the telescopic views of the moon. The bed of Cherry Brook may be seen in the view, lying diagonally across the picture, and between two roads. Later two views were taken near Simsbury.

At one time, when near the upper surface of the cloud, and at a height of 5700 feet, my attention was called to an immense cloud which we were rapidly approaching. I would state here that while the clouds were moving east, the current of air above the clouds was going in the same direction, but much faster, so that the large cloud mentioned seemed to be coming rapidly towards us. The camera was quickly made ready, and when the cloud was about one hundred feet from us, I fired; the next moment the car swung through the top of the cloud, and a wave of cold air, like a blast from an ice-house, passed over us. During the few moments from our first notice of the cloud to our plunge into it, we gave

* I asked Mr. Moore why he lifted his foot so high in crossing from one side of the car to the other. He said, "But look down there, and you'll see I'm stepping over two towns."

it our undivided attention; in its swift and silent approach, with the huge mass slowly unfolding, and fleecy particles tearing off in the wind, with the outer surface white in the sunlight, and with clefts in the mass dark as night, it seemed as though about to swallow us up for ever.

We passed over the mountains north of Talcott Mountain, and enjoyed the same prospect which is spread before those who climb the tower, but our view must have been much more extensive in its grandeur. The tower, always a prominent object to travellers upon the roads in the Farmington Valley, we had difficulty in finding, as it is of a neutral colour, and from our position above was not at all conspicuous.

When directly over the mountain we looked down at the forest and roads beneath us, endeavouring to discover some sign of human occupation or activity. To all appearance the country might never have been visited by man; the forest was thick, except when broken by some bare ledge or precipice, and, almost upon the highest part, a lake nestled among the trees, which grew quite to the water's edge. This little lake, almost circular in form, closely surrounded by the unbroken forest, the surface without a ripple, and its waters lying dark and apparently unfathomable, presented a picture of silence and solitude which held our attention while it remained in sight.

The mountains crossed in this delightfully easy manner, we were over the town of Bloomfield; and an exposure was made on what seemed to us a fine type of the better class of New England homestead, which, with its large fields, trim fences, and ample buildings, was directly below us. This view, taken at the height of one mile, is wonderfully distinct, when we consider the distance of the objects from the camera, the conditions necessary to the taking of an instantaneous picture, and our very unsteady support. The stone and rail fences, bounding the fields of all sizes and shapes, are shown with great sharpness. The pasture, meadow, and cultivated land are plainly indicated; also the curiously regular arrangement of the crops. The trim and regular appearance of the orchards is well contrasted with the variety and freedom of growth in the woodland; and the photographic effect of the autumnal colours is indicated by the foliage of a group of white birches near the centre of the view, as contrasted with the dark, unchanged green of the orchards.

Our view towards Hartford at this time was very interesting, though the smoky atmosphere in that direction was a great obstacle to photographing. The Capitol reflected the sunlight from its dome, and many of the prominent buildings of the city could be distinguished. A line of clouds hung over the country south of Hartford, cutting off the light, and producing the singular effect of a view under a shelf or table. The Connecticut River was in sight for many miles above Hartford, until the thickening haze cut off the light far to the south. We were astonished at the number of abrupt turns in the river between the city and Wethersfield.

As we were so nearly there, and sailing in exactly the right direction, we were anxious to remain in the upper air current, and land in Hartford; in order to do so, we threw out all our remaining ballast; the balloon still descended, and soon we saw that our hope must be abandoned, as the lower current began to take us away from the city and in the direction of Windsor.

When we had secured a view of Windsor and the junction of the Farmington and Connecticut rivers, Mr. Moore decided to land before going farther from the railroads; and, opening the valve to let the gas escape, we descended rapidly.

The point selected for our landing was an open field near a large tract of woods; but such calculations are very liable to failure, owing to the difficulty of estimating distance and rate of motion of the balloon, and it was soon evident that the wind would take us over the woods before we could reach the ground. As we had already thrown out all the ballast, and did not wish to sacrifice the photographic apparatus, we could only let things take their course; but we wished for a few pounds of sand, by the loss of which we might have cleared the woods and found a better landing-place.

The balloon sunk rapidly, and soon, as before, we heard the sound of the wind in the trees; we looked anxiously to see where we should strike, but were not long left in doubt as we passed quickly down beside a large chestnut-tree, and the netting of the balloon, which curves far out on each side caught in the upper branches, when our fall was suddenly checked. At first the weight of the balloon and load, descending with such force, bent the top of the tree far over; then, as our momentum was gradually checked, there was a recoil which lifted us again about fifteen feet, where we hung, planning how we should get the balloon down. We could not climb out, for then the balloon, relieved of our weight, would rise and leave us; but, after much hauling and jerking, the netting was detached from the tree, and we were on the ground again. Even then we were but little better off, as no one appeared to help us, and if one left the car the other would surely go up again.

Considerable gas was allowed to escape, and then, while I held fast to a bush, Mr. Moore climbed out and secured our anchor-rope to a tree; then I made my escape, and, leaving the balloon pulling at its moorings, we started to find help. After walking nearly a mile we met two men and a little boy, who asked if we "had seen anything of a balloon around there."

The balloon had fallen near a road cut through the woods, and we determined to get it to the road if possible. To do this, we persuaded the boy to get into the basket, in order to overcome part of the buoyancy,

and let the balloon up the length of the anchor-rope. We were then able to work the rope through the trees, and so led the balloon out to the road. But when we tried to tow it along to the clearing we quickly found it impossible, and the balloon was hauled down and ripped to let the gas escape, as the trees were too near together to admit of the usual practice.

A man was found to carry the balloon to the railroad and us to Hartford; and during the ride there I busied myself trying to recall the experiences of the ascension. As on the former occasion, I observed a singular loss of memory. Immediately after the excitement of landing it was hardly possible to recall a single incident of the ascension. I seemed to have just awakened from a wonderful dream, and the startling experiences so recently passed through appeared to have left only the faintest traces upon the mind. It was not until I had retired for the night, and would have slept, that memory revived, and I was treated (unwillingly) to a complete review of every incident connected with our trip. I am told that this has often been the experience of the soldier after passing through the dangers and excitements of the battlefield.

IMPROVEMENTS IN PLATES AND THE LIKE FOR PHOTOGRAPHIC PURPOSES.

No. 5793. JEAN BAPTISTE JOSEPH JOURNOUD, Lyon, France.—*April 28, 1886.* This invention relates to the application of celluloid, xylonite, and the like to photography by using celluloid, xylonite, or the like plates for negatives and positives, as also by replacing the ground-glass in the camera by translucent plates of celluloid, xylonite, or the like.

Glass, paper, cardboard, metal, and other materials used in photography up to the present for negatives and positives present serious inconveniences. Glass is breakable, heavy, and cumbersome, faults particularly serious for travelling and for the country. Paper, cardboard, and metal plates possess an opacity which renders the watching of the development exceedingly difficult, and prevents the operator from precisely assuring himself of the reduction of the silver film by the cyanides and hyposulphites.

To obtain at once the necessary rigidity, lightness, and resistance to breakage and warping by the action of the water bath and reagents, as well as the necessary transparency or translucency, I employ thin plates of celluloid, xylonite, or the like.

Having now particularly described and ascertained the nature of the said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. The employment of plates of celluloid, xylonite, or equivalent cellulose-product as the support or foundation for negative or positive photographic images or productions. 2. The employment of plates of celluloid, xylonite, or equivalent cellulose-product for the focussing plates of photographic cameras.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
May 17	Glasgow & West of Scotland Am.	180, West Regent-street, Glasgow.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. James Glaisher, F.R.S., President, occupied the chair.

The HON. SECRETARY read a letter from Mr. G. M. Whipple, of Kew Observatory, saying that at a forthcoming meeting of the Royal Meteorological

Society the exhibition of some photographic prints of flashes of lightning would have a special interest, and he should be glad of the loan of any such prints from the members of the Society who had taken them.

The PRESIDENT said that neither Mr. Spurge nor his paper for that evening had arrived, and that a sub-committee had suggested for discussion the question, What was the most practical method of obtaining photographs not less than 12×9 inches in dimensions?

Mr. J. TRAILL TAYLOR said that the best plan was to take a negative and to print from it upon albumenised paper. What idea was underlying a question so obscurely phrased?

Mr. T. SEBASTIAN DAVIS responded that the cameras of amateurs rarely took plates larger than 7×5 or 8×5, and a picture of such small dimensions quite lost its effect when put on view in a public exhibition; a larger camera in the field would have to be carried by a Hercules. What was the best way of enlarging to not less than 12×9? Direct enlargements on gelatino-bromide paper usually had a heavy effect, so what was the best practical method of obtaining the desired size? He had found it best to take the largest practicable negative in the first instance, because with it any minor blemishes were less apparent in the finished work.

Mr. TAYLOR stated that some of the best photographers, like Mr. W. Bedford, for instance, produced large pictures of admitted excellence. Although a good plan obviously was to take a small negative and enlarge it afterwards, yet would it be desirable to inquire whether Mr. Bedford would not prefer taking his large negatives direct, than to enlarge from those of smaller dimensions.

Mr. W. BEDFORD had never made any secret of the process he used; he preferred negatives of the required size taken direct in the camera, for there was a great loss of effect in enlarging, because when enlarging is done by producing an intermediate transparency, although the defects of the method can be modified to a certain extent, he thought that they were always apparent. He had had but small experience in enlarging direct upon paper, but he did not see why very good pictures could not be taken direct upon platinum and other slow papers by means of the solar camera. Once he made an enlarged transparency, printed a negative from it upon paper, then waxed the latter, which process was devised by Mr. Blanchard. He thought it well never to enlarge beyond the standard size of a sheet of albumenised paper, because then colour was much missed.

Mr. VALENTINE BLANCHARD had devised the process just mentioned about twelve years ago, and even Mr. H. P. Robinson did not know that some of the results were enlargements until his closer attention was called to the prints. Mr. Dixon's prints of animals had been taken by the same process. The printing must be very deep before waxing, and as it is easy to turn out a hundred or more paper negatives in this way, it facilitates the production of prints in long numbers. Mr. Dixon used for the purpose a specially prepared autotype paper, and he intensified with permanganate of potash. The transparency should be as solid as possible, developed deeply like a negative till all the details were well rendered. This mode of procedure was absolutely necessary.

Dr. W. F. DONKIN remarked that smaller pictures than those named in the question had gained medals at the exhibitions.

Mr. DAVIS thought that they would have been better if enlarged.

Mr. DEBENHAM remembered many good small pictures at exhibitions.

Mr. SAMUELS said that small pictures sent to the exhibitions received due attention from the judges. Take, for instance, *Improving the Understanding*, also *Neddy's New Shoes*. The little direct picture of the latter attracted more public attention than the enlargement thereof.

Mr. EDGAR CLIFTON remarked that gelatino-bromide paper offered a ready mode of obtaining the transparency for Blanchard's process.

Mr. W. ENGLAND had seen good results direct on bromide paper.

Mr. DAVIS stated that desirability of size depended much upon the subject; mountainous scenery did not look so well in small prints.

Mr. FRIESE GREEN asked whether the Society could not establish weekly classes for the errand-boys and assistants of photographers, the members taking their turn to instruct the learners.

Mr. AYRES suggested that they should be taught the extraction of the square root.

Mr. W. M. ASHMAN thought that there was something in Mr. Green's suggestion, although it had been a little crudely put. One of their Vice-Presidents, Mr. John Spiller, had recently given lectures to a class of students in the City, and such able teaching as his was very valuable indeed, for he brought up processes long forgotten. Mr. Spiller should be consulted on the subject.

The PRESIDENT thought that while the Society was but in lodgings, its new efforts in any direction must be very limited. Several persons had offered to give £20 for taking permanent premises. He had put his own name down for £50, and if a sufficient number of persons would put their names down for £100 he would increase his subscription to £100.

Mr. CARLAND said that he would contribute £10.

The PRESIDENT asked what was the best method of intensifying?

Mr. DEBENHAM thought it strange that the method which he had found better than any other was still so little used. He applied iodide of mercury to the film, well washed it, and then applied a solution of Schlippe's salt. His oldest negatives intensified by that method had been taken seven years ago, and were still unchanged. The negative must be perfectly fixed by sufficiently long immersion in the hypo, and the washings between the various stages must be thorough. If bichloride be used instead of iodide of mercury, it must be acidified with a little hydrochloric acid.

Mr. W. COBB thought it a complicated method, since there had been of late no difficulty in getting plates to give negatives of sufficient density. When, however, the negative wanted a little "picking up," he applied a very weak solution of bichloride of mercury, say, ten or twenty drops of concentrated solution diluted with twenty ounces of water.

Mr. ENGLAND could corroborate what Mr. Cobb had said, but he applied ammonia after the mercury.

Mr. ASHMAN said that Mr. England bleached the image first with mercury, then applied the ammonia.

Mr. COBB took care not to reach the bleached stage. The weak mercurial

solution had no visible effect at the time of application, but the added intensity became evident in the drying. If the action of the mercury were too prolonged, the intensity of the image would be reduced.

Mr. BAUM knew nothing better than mercury followed by ammonia, and had never known a negative so intensified to fade.

Mr. DEBENHAM had found Mr. Cobb's plan to answer only when the negative wanted but "a little picking up." The popular verdict as to Mr. Baum's method was that such negatives were not permanent; moreover, the method seemed to be limited to but one degree of intensification, which might or might not be the one required.

Mr. C. W. HASTINGS was elected a member of the Society.

The PRESIDENT said that at the next ordinary meeting of the Society Mr. E. Crookshank would read a paper upon *The Use of Photography in Microscopic Research*. The latest date for receiving pictures for the next exhibition of the Society would be September 21; the *soirée* would be held on October 1.

The meeting then broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, May 5, at the ordinary weekly meeting of the above Association, held at the Masens Hall Tavern, City, London, Mr. A. L. Henderson presided. There was a large attendance.

Mr. F. W. COX asked whether a wooden sink lined with lead would be a good one for ordinary photographic purposes.

Mr. W. E. DEBENHAM responded that such sinks were almost universally employed.

Mr. A. COWAN stated that there was nothing better than a plain wooden sink with a wooden gridiron on the bottom, all coated when very dry with melted paraffine wax.

Mr. J. B. B. WELLINGTON exhibited some orthochromatic prints of yellow flowers.

Mr. W. M. ASHMAN, in the absence of Mr. Spurge, produced prints the outcome of experiments done by Mr. Spurge with his sensitometer.

Mr. DEBENHAM thought that any one but the producer would have difficulty in explaining the meaning of the aforesaid prints.

Mr. W. BEDFORD remarked that they illustrated the effects produced by variations of the proportions of the components of the ordinary pyro-bromide-ammonia developer, and that Mr. Spurge preferred platinum paper to albumenised paper for obtaining true gradation in printing.

Mr. DEBENHAM thought that the temperature of development might have affected the results.

The CHAIRMAN regretted that Mr. Spurge was not present.

Mr. F. A. BRIDGE exhibited photographs of the pantomime of *Bluebeard*, taken in about twenty seconds by him at the Standard Theatre in 1879; some lovely fairies rose up when they should not have done, so were blurred.

Mr. COWAN thought that they were over exposed.

The CHAIRMAN exhibited an actinometer made by Messrs. Taylor, of Leicester, which seemed to him to be a well-made and well-thought-out instrument, although he had not yet tried it practically. To describe it would necessitate the use of diagrams.

Mr. DEBENHAM said that it would only test the visual power of the light, but with that information the experienced photographer could form some idea of its actinic power.

Mr. E. CLIFTON remarked that by it the strength of any desired portion of the image could be ascertained, and that was an advantage.

The CHAIRMAN exhibited an actinometer, made by himself, having somewhat the appearance of a chromatope; it consisted of a ring of holes glazed with various thicknesses of yellow-stained gelatine and of a movable ring of holes similarly glazed; the one ring moved over the other when a handle was turned. In use he adjusted a pair of superimposed holes to that thickness of gelatine layers which just prevented him from seeing the sitter when he looked through them.

Mr. CLIFTON thought that blue layers would have been better, and would have given some idea of the actinic power of the light.

Mr. WELLINGTON wished to know the best way to intensify collodio-bromide negatives without the use of silver; he had found that any over treatment with mercury gave them a nasty colour.

Mr. A. MACKIE asked if he had tried the intensifier of the Platinotype Company, which gave splendid coffee-coloured negatives; he believed that it contained platinum and mercury.

Mr. W. M. ASHMAN suggested intensification with silver and fixing in cyanide of potassium instead of hypo.

Mr. A. HADDON said that a correspondent who had asked THE BRITISH JOURNAL OF PHOTOGRAPHY the best way to restore a negative stained from the mercury not having been thoroughly washed out, had been informed in reply that such stains could seldom be removed, but that the application of cyanide of potassium could be tried. He thought that to be a wrong method, and that weak hydrochloric acid would have the desired effect, with a subsequent washing, and, finally, an application of ammonia.

Mr. WELLINGTON thought the chief cause of stained gelatine negatives to be imperfect fixation.

Mr. MACKIE was of the same opinion.

Mr. H. M. HASTINGS had had some platinotype paper given to him which had been kept for six months and was believed by its owner to be perfectly useless, but he had nevertheless succeeded in getting an unfogged print upon it by the use of a hypochlorite, in the manner he had described at the previous meeting of the Association.

The meeting then broke up.

CAMERA CLUB.

On Thursday,* April 28, members and friends gathered to hear Mr. Lyonel Clark read an account of his recent trip to the Spanish Main. Mr. J. Traill Taylor occupied the chair.

* Supplementary in part to previous notice

A most interesting lecture was delivered, and the address was illustrated by lantern slides made from negatives taken by Mr. Clark on the journey.

Previous to the lecture, and in response to the invitation of the Chairman, Mr. Clark showed a new washing and drying rack for negatives, the invention of Mr. Blackmore, in which the negatives are slipped into grooves and immersed in a pail or pan of water; when sufficiently washed the rack can be hung up and the negatives dried. On removing the plates the rack folds up and can be hung up out of the way. It is especially convenient for travelling.

Mr. G. Davison showed an excellent negative on the new Froedman film, taken the previous day at Burnham Beeches. This film is manufactured by the Woodbury Tissue Company. It is treated like an ordinary negative, no stripping or special manipulation being required.

Mr. Ferrero showed some interesting experiments on the rapidity of shutters, made by photographing a white spot on a bicycle wheel revolving at a fixed rate. Funnell's shutter gave, at 0, one-fourty-sixth of a second; at shortest possible exposure, one-sixty-ninth; set at one-quarter of a second, it gave one-seventeenth. Lancaster's Instantograph gave one-thirty-fourth of a second. The "Mary Ann" varied from one-tenth to one-twenty-seventh of a second, according to elastics used. Drop shutter gave one-twelfth of a second without elastic band, and one-twenty-seventh with. Prints were handed round.

Mr. Clark showed some travelling bottles manufactured by Messrs. Hinton & Co. The glass bottle is protected by a metal case opening with a bayonet joint; a spring in the top keeps the bottle in place.

Some slides of the group taken at the recent excursion to Hayes by Messrs. Dresser and Barclay were shown, and also a very interesting slide of a negative taken by Messrs. Lyonel Clark and W. H. Hyslop at the St. James's Theatre. The negative was on a plate isochromatised by Mr. Hyslop. The exposure was ten seconds, with the ordinary gaslight of the theatre, no limelight even being used, and the details were well shown on the slide.

The SECRETARY drew attention to the Club excursion to Gomshall, arranged for Saturday, May 14.

At the meeting held on May 5 the first set of lantern slides sent by the American societies in exchange with the Camera Club was again exhibited previous to distribution. A good company assembled, and the exhibition gave very great pleasure. Mr. W. A. Greene occupied the chair, and, at his invitation, the HON. SECRETARY drew the attention of those present to some very fine photographs of theatrical scenes at the Criterion, taken by Mr. J. F. Roberts. These photographs were taken by the ordinary light of the theatre in April last, and show some of the best and most finished work of the kind ever done.

Some slides made by Mr. Roberts from his negatives, and also others showing groups by Mr. Barclay, taken at the Burnham Beeches Club excursion, were put through the lantern. The American slides were then shown. The collection includes a very great variety of interesting subjects, amongst the best of which were tow boats on the Ohio and other river scenes. Some very picturesque bits by Mr. Slettenius attracted much attention, as did also several humorous subjects with children and pictures of winter scenes and yachts racing.

The 1887 International Exchange is in course of arrangement, and it is hoped that equal success will attend it.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held on Tuesday, May 3, 1887, at Myddelton Hall, Islington, N., Mr. J. Humphries, F.S.A., Vice-President, in the chair, Messrs. B. B. Fuller and G. Mengel were elected members of the Society, and Messrs. — Cusworth, J. G. Hilton, and E. Purton, were proposed for membership.

Mr. A. MACKIE, Vice-President of the Society, then delivered a lecture on *The A B C of Photogenic Emulsions* [see page 293].

Mr. F. W. Cox inquired whether collodion emulsion plates were quick enough for negative work.

The lecturer replied that plates from emulsion made by the method he had demonstrated would make good negatives, but were very slow indeed. A much quicker emulsion might be made with an excess of silver, but then greater care was necessary in the manipulation.

The CHAIRMAN inquired how collodion emulsion could be made to give an image of a warm tone.

The lecturer replied that the colour of the image was to a great extent dependent upon the exposure given, a long exposure and restrained developer giving a warm tone.

Mr. J. TRAILL TAYLOR, President, said that in the early days of gelatine Mr. Burgess made emulsions of great sensitiveness; he did not disclose his process, but his method was probably similar to that of Mr. Bennett. Mr. Kennett also made very sensitive plates, but had extreme difficulty in inducing his patrons, who were accustomed to collodion, to give sufficiently short exposures. Mr. Kennett sold his emulsion in the form of dry pellicle. Mr. Taylor believed that if it could be obtained in this form now it would be of great convenience to photographers in the colonies and elsewhere.

Mr. W. M. ASHMAN said that this was his first visit to the Society. He congratulated the members on having heard an able lecture, in which all the ground connected with emulsion making had been covered. He thought the meeting would like to hear something about the methods employed in coating gelatine plates.

The lecturer said that his lecture professed to treat of emulsions only, and not of the method of using them. However, it was necessary when plates were to be coated to prepare a level surface, say of glass or slate, upon which to lay the plate until the emulsion set. The emulsion was flowed over the plate in a somewhat similar way to coating plates with collodion.

Mr. E. CLIFTON said, with reference to the keeping qualities of collodion emulsion, he had purchased a bottle of Messrs. Wratten & Wainwright about seven years ago; two years ago, that is, five years after it was made, he had prepared plates from it which he exposed and developed, producing perfect results. He had still some left, which he shortly intended to test again.

In reply to Mr. Taylor, the lecturer said that he had, in the early days of gelatine emulsion, used camphor to prevent the emulsion from decomposition when it was required to be kept. Thymol, however, was now more frequently used, and acted perfectly efficiently.

The lecturer, having been asked by the Chairman for a general reply to the remarks of the members, said that he had endeavoured to reply to questions as they had been asked. His intention in giving the lecture had been to say sufficient on the subject to enable any one to take any published method of making an emulsion and to understand not only the instructions but the theory upon which they were based.

The proceedings terminated with a hearty vote of thanks to the lecturer.

Saturday afternoon outing, on May 14, to Hendon. Train, forty-one minutes past two from Moorgate-street. Next meeting on Tuesday, May 17. Demonstration by Mr. Walker, of the Eastman Company. Visitors are invited.

NORTH STAFFORDSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting was held at the Mechanics' Institute, Hanley, on May 4, under the presidency of Mr. C. Alfieri, President of the Association.

A list of eight excursions for the season 1887 was drawn up, and their approximate dates arranged, the places selected being Buxton and Miller's Dale for May. Afterwards Dovedale, Haddon and Asford, Trentham, Keele, Moreton, Tutbury, and Lichfield, due notice of which will be given to members by the Hon. Secretary.

Messrs. Drummond and G. Wright were elected members of the Association.

The opinion of members having previously been obtained by circular, it was decided that the annual subscription be in future reduced to 5s.

The PRESIDENT exhibited a beautiful 12 x 10 silver print of a ruined abbey in Denbighshire, the negative of which he had himself seen Mr. Francis Bedford take thirty years ago. The print was one of the first taken from the negative, and was almost as good as when first produced.

Mr. LECK was then called upon by the President to read his paper upon the *Fascinations of Photography* [see page 297].

This was listened to with great attention, and a vote of thanks passed to Mr. Leck for his interesting and instructive lecture.

HALIFAX PHOTOGRAPHIC CLUB.

The monthly meeting of the above Club was held on Thursday evening, in the Mechanics' Hall,—Mr. E. A. Caw in the chair.

A paper on *The Bromide Paper Process* was read by Mr. B. ROWLEY. He thought it possessed special advantages for producing pictures from negatives, which from their thinness or over density could not be utilised similarly by any other process. Time would be required to test the permanency or otherwise of results. If it was possible to eliminate the last trace of hypo, there did not seem to be any reason why a bromide paper picture should not be as permanent as any other kind. Speaking of the different kinds of paper in the market, he had well tried the Eastman, Morgan & Kidd's, and Fry's makes, and had no hesitation in saying he could do good work with any of them, and that he considered them equal in quality.

The Secretary was instructed to write to some of the Photographic Societies in the neighbourhood with a view to arrange joint excursions during the summer months.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

The annual meeting for election of office-bearers for the next session was held in Lamb's Hotel last Thursday, when the following were unanimously elected:—*Hon. President*: Dr. Cammelly, University College.—*President*: Mr. G. D. Macdonald, F.I.C.—*Vice-Presidents*: Dr. Tulloch and Mr. John Robertson.—*Council*: Messrs. Geddes, Fraser, Kerr, Mathewson, J. R. Wilson, G. A. MacLaren, Martin, Hill, and Owen.—*Treasurer*: Mr. V. C. Baird.—*Secretary*: Mr. James Rattray. Mr. James C. Cox was unanimously chosen as the delegate of the Society to the Photographic Convention to be held in Glasgow in July.

Correspondence.

✉ Correspondents should never write on both sides of the paper.

M. CHARDON ON EASTMAN'S PAPER.—ENLARGEMENTS BY NADAR.—A NEW ANTI-PHOTOGENIC FILM FOR WINDOWS AND LANTERNS.—HOW TO OBTAIN GOOD ENLARGEMENTS WITH EVEN AN ORDINARY NEGATIVE.—A ROLL HOLDER OR DARK SLIDE FOR FILMS.—A POCKET CAMERA.—A NEW DODGE IN ENAMELLING PHOTOGRAPHIC PROOFS.—PRESENTATION OF CAMERAS AND FILM HOLDERS.—A POCKET CAMERA WITH A VERY NOVEL APPARATUS FOR CHANGING PLATES.

The Photographic Society of France held their monthly meeting on Friday evening last, the 6th instant, M. Barly in the chair.

M. Chardon made a communication on the value of Eastman's paper for amateurs and others.

M. Nadar exhibited some very fine enlargements on Eastman's paper, one of which was about two yards high. These enlargements were greatly admired by all present.

M. Seola exhibited some glass plates having an orange-red tint, which, he stated, were very suitable in replacing the very expensive ruby glass in dark-room windows, lanterns, &c. He informed us that he obtained that tint by coating the ordinary white glass with a solution of gelatine

in which a little silver nitrate had been dissolved. This is the formula he gave,—

Water	100 parts.
Gelatine	5 "
Silver nitrate	1 to 5 "

It can be seen that more or less silver is used according to the density of the colour required. In my judgment the best results were obtained by M. Scola when he used four parts of silver nitrate. When the plates or sheets of glass are coated with the solution they are left to dry in the dark; when thoroughly desiccated, they are placed in full light for ten or fifteen minutes. They then become of the yellow-ruby tint required. The plates are then plunged into a solution of hyposulphite of soda. When washed and dried they are ready for use.

M. Scola informed us that the plates when coated (as soon as the emulsion be set) can be exposed to light, and the same results as to colour be obtained; but the plates, when exposed wet, gain a very disagreeable reflecting property, which is not a gain, but rather a loss, to the purity of the colour obtained, and for which the short exposure required to obtain a corresponding tint does not offer a compensation. It has been found more advantageous to allow the plates to dry in the dark than to expose them when wet.

These experiments of M. Scola are very interesting, and deserve to be repeated. They may, I think, give us a clue which may lead to the discovery of the cause of the formation of the red fog, which we heard so much about in the advent of gelatino-bromide of silver preparations. I would most willingly have conducted a series of experiments having this object in view, but, alas! my establishment in Paris has been destroyed by fire, and I have not a room in which I can develop a negative at the present moment.

M. Nadar exhibited a very fine enlargement on Eastman's paper of the members of the Astronomical Conference. The enlargement is three feet by two, and was obtained from a half-plate negative. The enlargement, in fact, was far superior to the original negative. This gave rise to a discussion, and a communication by a member, *How to Obtain Good Enlargements with more than Ordinary Negatives*. The author said: "I reproduce the faulty negative in the camera on one of the old-fashioned collodion dry plates. Major Russell's tannin process is the best. Gelatino-bromide of silver plates must be discarded," he said.

In developing the *cliché* one is surprised to discover details come out of which the original negative seems wholly devoid. Naturally, a skilled operator alone can produce a first-class positive in every way satisfactory for the object in view—the enlargement. A negative was shown round accompanied by a positive obtained under these conditions. A proof from the same negative was then shown, and a proof from a negative obtained from the positive was handed round. The difference in the two was extraordinary. In the first, confusion; in the second, detail—in fact, a high-class negative. The enlargement was then shown, and was worthy of an exhibition.

M. Mario Carquero presented his perfected roll holder or dark slide for negative paper, which for simplicity and lightness leaves all others behind. The spool bearing the sensitised paper is movable, and can carry twelve yards of film, and when this is used up the spool can be taken out and replaced by another spool in full light, which is a great advantage to the amateur on a tour. After each exposure the paper is pricked across its whole width like postage stamps. For travelling the spool can be taken out; then the mahogany frame folds up and lies perfectly flat. This roll holder was greatly admired, and the maker was complimented in that he had combined simplicity with strength, and at a very low sum (20s.), which would incite other amateurs to dabble in photography. A great number of landscapes were exhibited to prove the value of the apparatus.

M. Mendoza exhibited a pocket camera. This apparatus differs but little from the numerous pocket apparatuses now in the market. A seeker is adapted to the apparatus, consisting of a kind of reversed telescope with a ground-glass, on which is portrayed the object to be photographed.

M. Vidal informed the Society that he had thought of a dodge by which in enamelling photographic proofs an artistic border or frame with the name of the photographer or any other inscription could be had at the same time and without any difficulty. Every one knows the engraved glass panes in the centre of which carbon proofs are placed, intended to be hung at the window so that the proof can be seen by transparent light. The engraved and ornamented border of the glass makes a whole agreeable to the eye. M. Vidal takes one of these engraved glass plates, the centre of which is of the size of the print to be enamelled—naturally the centre is of plain glass, the ornamentation the same, all the rest of the plate is of ground-glass. This engraved plate is talced, and the photographic proof, obtained by the gelatino-chloride of silver process, is laid and squeeged upon its surface; when dry the print will leave its support, and the paper will be beautifully glazed upon the print as well as upon the design—the latter will stand out upon a matt ground. Naturally proofs will be more expensive, as the proofs are printed with a large margin, which margin must be hid from light during the operation of printing. The ordinary albumenised proofs can be enamelled as well, by operating in the same fashion as those who enamel in the so-called "Parisian style"—collodionising the plate in the first instance and then making the proof adhere to the collodion by gelatine. Many changes can be rung

upon this idea; the engraving alone may be matt—this would give the whole of the paper brilliant with the exception of the design, which could be matt. In fact, it is not necessary to go to the expense, now I think of it, to print the proof with a large margin—a sheet of coloured paper can be enamelled and the print placed in its centre, which would have a very pretty effect.

M. Mackenstein presented a camera of his make, together with a film carrier; this consists of thin zinc of a quarter of an inch larger than the size of film required. This quarter of an inch is turned over and makes a frame. The film is inserted, and then a piece of ebonite is pushed down behind it, which stretches the film. It can now be inserted into any dark slide with the same ease as an ordinary dry plate.

M. Hanau exhibited a very small camera, which he has named "L'Omnigraphe." This pocket camera differs from many others in the market in that a new system of changing plates is adopted. The system is very ingenious. The camera contains twelve plates: as soon as No. 1 is exposed a drawer is pulled out holding the eleven remaining plates; No. 1 now falls down (I forgot to say that the camera must, during the changing of plates, be laid horizontally, the lens pointing upwards); the drawer is now pushed in and the second plate is ready to be exposed, and so on until the whole twelve are exposed. This invention will do away with the old-fashioned changing box, as the author says it cannot get out of repair nor clogged up in any way. Amateurs will be glad to know that films can be used with this apparatus as well as dry plates.

59, Rue des Batignolles, Paris.

PROF. E. STEDDING.

THE RIGHT TO THE NEGATIVE.

To the EDITORS.

GENTLEMEN,—Mr. G. A. Rattray in his last letter asks, "Is it not a fact . . . that photographers charge in their first price for prints, the cost of the glass, and all the chemicals and subsequent operations for the production of the negative?" (I presume Mr. G. A. R. by "subsequent operations" means lighting, and posing, and retouching.)

Let us take a case in point. B. is photographed and pays twenty-five shillings for a dozen cabinets. Twelve months after he again orders another dozen from same negative, but only pays this time twenty-one shillings. Does Mr. G. A. R. assert that the four shillings pays for plate and "subsequent operations?" It may be the money value of the plate, but certainly is not an equivalent for the skill and time of the operator and retoucher.—I am, yours, &c.,

OPERATOR.

Nottingham, May 9, 1887.

To the EDITORS.

GENTLEMEN,—Does it not seem highly curious that after about forty years of "use and wont," a discussion should arise about the ownership of photographic negatives?

My photo-professional career began at the middle of the century, and although my entries for sittings numbered for many long years far above a thousand yearly, and my sitters included the titled nobility as well as the better class of working people, not one of them ever claimed the negative as their own.

It did occasionally happen that a sitter on leaving for foreign parts took a fancy to the negative I had taken of him or her, and asked its price; and on every occasion, when an agreement was come to, I received my own price for the negative in question.

This even happened with more than one well-known person, and I may name Miss Hosmer, the celebrated American sculptor, who, after getting as many photographs printed as supplied her friends in this country, bought from me the negative I had taken of her that she might get what number of prints she wanted taken from it in Rome.

This practise I thought general, and one of

USE AND WONT.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, landscape lens (whole-plate) in exchange for good studio furniture.—Address, A. B., 656, Holloway-road.

Will exchange musical box for good 9x7 view lens.—Address, J. E. OATEY, Photographer, Wadebridge, Cornwall.

Will exchange an interior and exterior background in good condition for other backgrounds.—Address, ALLAN, 23, Fore-street, Hexham, Northumberland.

Will exchange a case (45x30) of stuffed birds for a studio stand, bellows-bodied camera, or backgrounds.—Address, H. H. HILL, East-street, Bridport, Dorset.

I will exchange quarter-plate mahogany studio camera complete, with light metal tripod, for quarter-plate lens.—Address, H. WHEATLEY, 17, Manchester-road, Hopwood, Heywood.

Will exchange 15x12 camera and two slides for whole-plate and double slides with latest improvements.—Address, GEO. SHERMAN, Pier Studio, Regent and Nelson-roads, Great Yarmouth.

I will exchange two volumes of the *Magazine of Art* (unbound) for 1885 and 1886 for quarter-plate bellows-body camera and double dark slide.—Address, JOHN CHALMERS, 43, Campbell-street, Hamilton.

- Wanted, Guerry's flap shutter, to fit Ross' 5x4 rapid symmetrical; exchange, a book of twenty-four drawings of the human figure, by Julien, of Paris, size 12x10.—Address, G. MAYBANK, 7, Ridge-street, Southwark Park-road, S.E.
- Will exchange studio camera, half-plate carrier, also quarter-plate camera and lens, and mahogany tripod stand, and pair of stereoscopic lenses. Wanted, head-rest, backgrounds, and accessories.—Address, W. HYETT, Suffolk Studio, Cheltenham.
- Wanted, half-plate camera lens, &c. ("International" preferred), in exchange for three-draw telescope, about thirty-six inches long, one-and-a-quarter-inch object glass, and tripod. Difference in cash.—Address, WM. HAINSWORTH, Upper Wortley, Leeds.
- I will exchange Cadett's shutter for any size lens, quarter-plate Rouch bellows camera with four dark slides and lens for same, also pair of stereoscopic lenses. Wanted, head-rest, studio camera stand, whole-plate outdoor camera with three or more double dark slides, and 12x10 wide-angle rectilinear lens.—Address, S. P. L. PHILLIPS, Photographer, Oxford House, East Croydon.
- I will exchange two fine marine oil paintings, size of canvas 32x18 inches, in massive gilt frames (*Sunrise at Sea*, by Nott; *Off Cape Race, Newfoundland*, by Haynes), for Ross' No. 3 portrait, or similar lens by any good maker. Also 9x7 single slide and focussing screen to match, by Menger, for cab net rolling press.—Address, W. P., Holmwood, Richmond Park-road, Kingston-on-Thames.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a *NOM DE PLUME* as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

- J. GRAY.—The examples sent are very good indeed.
- ALLAN.—We prefer acidulating with sulphuric acid.
- J. W. PHILLIPS.—Varnish with Canada balsam and benzole.
- ENLARGER.—Employ a sheet of ground-glass without any condensers.
- J. S. NETTLEFOLD.—The address of the Willesden Paper Company is Willesden, Middlesex.
- W. W. C.—Clearly your letter miscarried, as we have received no previous communication from you.
- F. H. BURR.—The particulars could not have reached us up to the middle of November, else would they have been published.
- F. G. S.—Although the orthographic will serve as an "all-round" lens, yet we would give the preference to one of the "rapid" series.
- CANNELL.—1. A nearly plain one, such as described in an article in a recent number. 2. A plain one, slightly shaded on the lower portion.
- H. P. PETERS.—As it is a simple rule of three problem, a lens of twice the focus of any other will give an image twice the linear dimensions.
- G. Y. G.—Under the conditions by which they were produced the transparencies are very promising. We should certainly advise you to continue your experiments to a successful issue. So far as you have gone the experiments are very interesting.
- C. RICHARDS.—Are you sure that the spots proceed from dust? It is not usual to take all the precautions you appear to have done in filtering the air before it enters the drying box. Your room must indeed be a dusty one if six or eight thicknesses of fine gauze do not remedy the evil. We strongly suspect the spots proceed from causes other than dust.
- P. D. R.—There ought to be no difficulty in changing such small plates as quarter size on board a steamship. Failing to obtain a suitable corner at night, a changing bag might be employed. As we are not familiar with that particular coast, we cannot express an opinion as to the quality of light there. The development of two or three trial plates will settle the question.
- SPOTTING COLOUR.—Thymol or salicylic acid added to the albumen will prevent it from decomposition for a considerable time, so will a lump of camphor kept in the bottle. The colours mentioned will be very suitable if mixed judiciously. Perhaps, however, instead of the Indian red a madder lake would be preferable, as it would enable the colour of the photograph to be better matched.
- A. F. M. says: "On page 269 of the *ALMANAC* I see a recipe for making a gelatine emulsion for opals, &c., without development. I should like to try it, but I do not see how the printing is to be managed, as of course one cannot turn back a sheet of glass as one does the paper to see how the printing progresses. Will you be so kind as to let me know, in the 'Answers to Correspondents,' how it is to be managed?"—Registering pressure frames are sold which enables the picture to be examined during the printing and replaced in exactly its original position. As an extemporary arrangement an ordinary printing frame may be used. In this case the negative is firmly fixed, say with gum paper, in one corner of the frame, then the opal plate is placed accurately on the negative and pressed firmly in the angle of the frame; it can then be examined and afterwards returned to its original place if the precaution be taken to place it accurately in the angle again.
- CARBON says: "I made a solution of gelatine and chrome alum for fixing carbon prints on opal or ivory; after using I placed it in a bottle until further required, and now find it has set so hard that I cannot melt it again, even by placing the bottle in boiling water. Will you kindly say, in next issue of the *JOURNAL*, if it is necessary to make fresh solution for every batch of prints, or is there any way of making this usable? The following is the formula used:—A five-per-cent. solution of Nelson's No. 1 gelatine; add to every ten ounces of above one ounce of a twelve-grain solution of chrome alum."—With this proportion of chrome alum the solution should be made only at the time it is required, because after it has once set it becomes insoluble. The best plan is to keep the solutions of gelatine and chrome alum separate and mix them as required. If a small quantity of thymol, carbolic acid, or other antiseptic, be added to the gelatine solution, it may be kept free from decomposition for a long period.

WILLY EDELSTEIN writes as follows:—"About three months ago I worked a negative of Miss Gilechrist for Messrs. — on approval. I was to call and hear their decision, and did so twice. They still could not decide, and promised to come to me. I did not hear from them, so I wrote and asked them kindly to favour me with a reply as promised, but had none. I left London, and returned only last week for a few days, and saw the very photograph I retouched published in several different places. So I wrote to the gentlemen, and said that I was glad to see my work exhibited, and should still like to know the reason for their not answering and not paying me for the work as promised. Then they sent 4s., and said the reason they did not write was because they did not consider my work satisfactory enough. Now, do you think Messrs. — would exhibit a photograph that was not retouched good enough? Of course, I returned the 4s., and told the gentlemen that I could not possibly accept the pay for unsatisfactory work, as they considered it; but they have not acknowledged the receipt of it as yet."—If our correspondent's statement be correct, it is surprising that a West-End firm with the reputation of the one named should act in this manner.

NEMO writes: "I am much obliged for your answer to me in your last issue concerning a positive bath and developer. I have made both carefully according to your directions, but fail to get anything like a clear picture. The bath I have tested with blue litmus paper, which it turns pink (the amount of nitric acid being two drops to eight-ounce bath), and was carefully filtered. In developing, the picture appears in a few seconds, and before any detail appears in the shadows I wash well and fix (cyanide of potassium, quarter of an ounce; water, ten ounces). As the picture is being cleared by the cyanide solution numerous streaks and comets make their appearance, otherwise the pictures would be all right. I cannot put these streaks, &c., down to the collodion, as I was working with a fresh bottle at the time. I may add that these streaks do not appear to be refuse solution flowing down the plate from the wire corners of the carrier, as more often than not the corners are clear while the centre is nothing but a mass of streaks and comets. To the developer I added one ounce and a half of alcohol (methylated). Is this about right, or should I have used *absolute* alcohol? If so, about what quantity would you think sufficient? I should be much obliged for any information that would help me to get over this little difficulty."—The comets, like the streaks, may proceed from different causes. The former may be due to floating particles in the collodion. After iodising this should be allowed to settle for a day or two and then carefully decanted before use. The comets may also arise from particles in the developing solution. In this case filtration is the remedy. The streaks are most probably due to the plates being removed from the silver bath too soon. Methylated spirit will do quite well for the developer, provided it be free from gums. If any gum be present it will very likely cause trouble.

RECEIVED.—Transactions of Leeds Photographic Society; J. W. Blase; F. Barber, and others.—In our next.

We have also received a sample bottle of Holmes's photographic ozone, a well known and highly appreciated agent for reducing the density of gelatine negatives.

MR. WILLIAM TYLER has favoured us with an opportunity of examining his metal dark slides. Although rather heavier than wooden slides, they are quite light-tight and ought to be very durable.

PHOTOGRAPHIC CLUB.—The subject for discussion at this Club, May 18, 1887, will be *The Production of Lantern Slides from Large Negatives*. Saturday afternoon outing at Highgate. Meet at Archway Tavern near two o'clock.

TRADE CATALOGUES.—Within the past few days we have received several trade catalogues, including those of Mawson & Swan, W. Wray, the London Stereoscopic Company, Lancaster & Sons, and others. These we shall notice next week.

MESSRS. HORNE, THORNTON, & WOOD have shown us a model of a shutter they are about to bring out. It acts on a principle similar to the Grinstead, of which we gave a full description a short time ago, only the motion is given both up and down by rubber bands instead of by an adjustable metal spring.

MR. C. A. FERNELEY, Reigate, sends us examples of his photographic practice in and around Reigate during winter, the ground being covered with snow. Mr. Ferneley designates them *melanographs*, from their colour. Although small they are good, and are printed on bromide paper, which lends itself well to winter scenery.

We have received a copy of the *Handbook and Guide* issued in connection with the Cyclists' Touring Club, which is compiled and published annually by Ernest R. Shipton, Secretary and Editor of the *Monthly Gazette* (140, Fleet-street, E.C.). We are glad to perceive that about three hundred and fifty of the hotels under contract with the Club have been induced to set aside a dark room for the use of such members as are photographers.

CORRECTION.—In our notice of Mr. Roberts's nocturnal photographs of *David Garrick* we spoke of his having followed the example set by Mr. Hyslop. "But," writes Mr. Roberts, "the 'example' is the other way round. My pictures were first taken on March 9, and were exhibited at the Camera Club on Thursday, April 14. (Why no mention is made of them in the 'Club Proceedings' under the report of that evening's meeting I do not know.) May I therefore ask that you will do me the favour to insert this correction?"

No. 1411. VOL. XXXIV.—MAY 20, 1887.

PHOTOGRAPHING FLOWERS.

PHOTOGRAPHING flowers and other small, inanimate objects, is becoming more and more a favourite pastime amongst amateurs, who, taking the cue, no doubt, from the numerous professionals who utilise such subjects for Christmas and birthday cards, find in them an endless variety of studies and a good deal of pleasant amusement, which, moreover, do not encroach very greatly upon either time or purse as an extensive landscape practice is apt to do. For those who elect to set up a speciality of this description nowadays, every facility is afforded by the modern gelatine process, which is far more than can be said of the wet collodion plates of a former era; and when such a line of practice is well and properly worked, and really first class results produced, it is quite as likely to attract the notice of the judges at the various exhibitions as are the conventional landscape, portrait, and architectural subjects which the great majority of photographers affect. Witness the numerous medals which have gone to flower and similar subjects at Pall Mall and elsewhere during the past few years.

From the numerous inquiries we are constantly receiving, we are made aware that great and serious difficulties exist, at least, in some quarters, in connection with the carrying out of this kind of work. Some few of these may be, no doubt, real, but we cannot help thinking that by far the greater portion are purely imaginary, and arise from deliberate neglect of the most elementary rules of common-sense on the part of those who make them. At any rate, work which was really difficult in years gone by is simple in the extreme with gelatine plates.

Some years ago we were consulted by an amateur friend, who was more deeply versed in entomology and conchology than in the mysteries of the camera, on the subject of photographing a large number of butterflies, moths, and shells. Our friend was himself the possessor of extensive collections of these various objects, and had, in addition, secured permission to photograph the objects in such classes in a large museum on the ordinary "students" days; and his idea was to publish a sort of catalogue of English and foreign butterflies, moths, and shells, illustrated by means of photography. Upon the probable value of such illustrations we need not at present dwell, suffice it to say, that after a very brief experience of the best that photography could do in rendering into monochrome the brilliant hues of tropical *lepidoptera* and the delicate pinks and yellows and browns of the *concha*, our friend determined to relinquish the task as hopeless, if not Quixotic.

Much of the colour difficulty then experienced has been overcome by gelatine plates even before the advent of orthochromatic films; but, quite independent of the incorrect rendering of yellows and blues, the extremely long exposures required, even

under the most favourable circumstances of light with some of the subjects, when wet plates were used—the most rapid by far then available—promised to render the task an almost interminable one.

But, in addition to what we may term the chemical and chromatic difficulties, there were others experienced in lighting the objects, and also in securing proper perspective; or, what it really amounted to, in obtaining *undistorted* reproductions of the originals. Besides these, there arose the difficulty of securing sharpness of the whole object unless an extremely minute stop were used. These last troubles were purely optical, and were owing to the fact that our friend's only lens was a portrait combination of short focus—in fact, a quarter-plate lens of four and a half or five inches focus. With such a lens, to attempt to reproduce in many cases almost, or fully, natural size an object in high relief, such as a heavy-bodied moth, was to apply it to an altogether wrong purpose, and it is scarcely to be wondered at that distortion and want of sharpness were the inevitable results. Then, again, with regard to the lighting, the shadows cast by the wings and bodies of the insects, and by the convolutions of the shells, were so heavy as to altogether destroy the form of the objects in their reproductions; and it was only when a box was "rigged up" to represent a small studio, giving as nearly as possible all front light except what was reflected equally from the four sides, that the obnoxious shadows were got rid of. But this, once more, added greatly to the time of exposure.

This, we must repeat, occurred with wet collodion, the sensitiveness of which to extremely feeble radiations is greatly inferior to that of gelatine. With modern plates under similar conditions we do not think the same difficulty would be experienced, for though the shadows would be cast, they would be rendered in a manner so subservient to the main object that their presence in the picture would cease to be objectionable.

From butterflies and shells to flowers appears at first sight a wide step, but it is not really so in this case, the facts and circumstances being in a measure identical. Colours as vivid and as varied, shades and *nuances* every whit as delicate, are to be found amongst our British flowers as amongst the most gorgeous of tropical insects; and we are met with this additional difficulty, that no matter how pale or delicate the blossom, it is invariably surrounded or accompanied by foliage of a more or less sombre green. There lies, in fact, the chief colour difficulty of the present day. Thanks to the introduction of orthochromatic plates, the due rendering of the blues, greens, and yellows is made comparatively easy; but the simultaneous reproduction in all their delicate gradations of the leaves and

blossoms of such flowers as camellias, gloxinias, and many of the orchids, forms the rock upon which most beginners in flower photography split. The common hawthorn, as well as such blossoms as those of apple, peach, and pear, are less difficult on account of the comparative lightness of the young foliage that accompanies them; yet to many they form almost insurmountable obstacles, though really perfectly easy if properly handled.

The optical difficulties of flower photography are also similar to, though perhaps greater than, those already alluded to. As in the previous case, the object is subject to but little reduction in the process of reproduction, and presents an even wider range of planes in proportion to the focal distance of the lens. Consequently, the difficulties of perspective and of securing an even focus are, if possible, greater in the case of flowers. We are not of that class who, on the ground that the eye only sees one object at a time sharply, hold that if the principal object in a picture be in focus, the artistic effect is enhanced by surrounding objects being more or less blurred. Such an argument may form a good excuse for a defective lens, or for want of care in arranging or focussing the subject, but it is illogical. True, the eye can only define sharply over an extremely limited area at one time, but it can direct itself, or be directed, to any part of a scene or picture which it is desired to examine closely; but in the case of a lens defining over so limited an area that only one object in the picture is sharp, the eye and the sense are confined to that one object, and imagination must, in a great measure, fill in the rest. Better, one would think, to emphasise the central object in some more legitimate manner, and leave the eye to do its duty in its own way.

Whatever may be the opinion on this question in connection with general subjects—portraits for instance—we think there can be little doubt that the result of such treatment of a flower subject would be offensive in the extreme, and the endeavour of the operator should therefore be to secure the best general definition possible. We do not mean to imply that every leaf and spray, every curve and marking, must be equally sharp, but that there should be no sufficient falling off in definition to give a blurred and indefinite appearance to the picture. This result can only be satisfactorily attained by employing a lens of long focus, as in so doing the difference between the planes of the object is rendered comparatively less, and the lens therefore requires less "stopping down," while at the same time a more natural replica of the object is secured owing to the absence of distortion or exaggerated perspective. The difference, as compared with the use of a lens of short focus with a small stop, is much the same as examining the object at a natural and comfortable distance and straining the eye to view it at extremely close quarters. Mr. Henry Stevens, whose large flower studies have been admired at various exhibitions during the past four or five years, owes much of his success to the employment of a lens of long focus.

We do not profess to lay down any rule on this point, but for our own practice we employ for a half-plate—a cabinet-sized picture—a lens of fifteen inches focus. If we resort to figures some idea may perhaps be formed of the difference likely to be produced by this lens and, say, one of six inches focal length. Suppose we wish to photograph a vase of flowers measuring twelve inches in height, and desire that it shall occupy four inches in the picture, or a reduction to one-third. With the fifteen-inch lens the camera, or rather the lens, will have to be five feet distant from the object, and the total distance between the object and the plate will be nearly seven

feet. With the six-inch lens, however, the distance from the object will be two feet only, and the total separation of the object and plate thirty-two inches. If a vase of flowers be examined with one eye closed at these two distances, the difference in the pictorial results will be at once recognised, and this takes no count of the improved optical conditions that prevail in the use of the longer focussed lens.

The next question is that of lighting, a much easier task nowadays, as we have hinted, than formerly. We have made comparative tests in the open air, under glass, and in an ordinary room, using the same object as well as the same lens and degree of reduction, and must emphatically give the preference to the last, when proper precautions are taken. The open air is for certain reasons out of the question for successful results, even if a vast flood of top light were desirable, for the weather is rarely such in our country that a spray of delicate flowers would remain undisturbed by air currents for a sufficiently long time to impress the plate satisfactorily. It is quite true that under the circumstances extremely short, even "instantaneous" exposures, may be given, but, as we shall show in treating of exposure and development, such conditions are not desirable.

Neither out of doors nor under a glass roof are altogether pleasing results produced owing to the amount of top light, which gives to the object an aspect under which it is unfamiliar to us, unless, indeed, we are accustomed to seeing vases or grouped sprays of blossoms in the conservatory. For single plants in pots or grouped under conditions in which they are likely to be seen under glass, the glazed roof may be used; but even under those circumstances we think better results are secured from a side and front light, with no more top than is gained from the height of the side light.

To gain this result the camera and object should be arranged in a line parallel with the window, the object being set back so that the light falls upon it from the window in an oblique direction. The further it is set back from the window in the direction of the axis of the lens the more will the illumination partake of the character of front light and the less necessity will there be for the employment of reflectors. The further the distance is increased in a direction at right angles from the window the less will be the contrast between the light and shadow side, the position being otherwise unaltered.

It may be observed that when the flowers are arranged in vases or vessels possessing highly reflecting surfaces it is desirable to remove the object as far as possible from the window, in order to reduce the patch of reflected light which will inevitably appear. This, if not too large, adds a finish to the picture, but if glaringly prominent it becomes offensive. If the containing vessel be of such a shape or nature that the window sashes or bars are reflected, these must be hidden by hanging tissue-paper over the window.

A large sheet of white cardboard should be at hand to act as a reflector to light the shadow side of the picture and to pick out the details in the interstices of the foliage. If a simple stand to hold the reflector at any angle be provided, so much the better; but it can be very well manipulated by hand, and in some cases where it is necessary to keep it in motion this is preferable. For some purposes, for instance, lighting up the shadows of heavy foliage, a small hand mirror is useful if direct sunlight can be caught by it; or if carefully used and manipulated so as to cast as little shadow on the background as possible, a short length of magnesium wire may be burnt as an auxiliary light.

The subject of exposure and development, together with a consideration of the employment of orthochromatic plates, must be left until next week.

AN AMERICAN DETECTIVE CAMERA.

HAVING recently received from the United States one of the most perfectly designed and executed detective cameras we have yet seen, we believe that a brief account of its construction will prove of interest.

Premising that it emanates from the Scovill Manufacturing Company, of New York, which is a voucher for excellence throughout, we observe that its general appearance when carried in the hand is that of an elegant case or cabinet richly covered with black morocco leather. Its dimensions are $10 \times 8 \times 6$ inches. Such is its appearance as a whole that it may be carried about in the hand in the streets, or in the railway carriage, without exciting the slightest suspicion or even attention.

On opening the lid it is seen that this unsuspecting-looking cabinet contains a 5×4 camera, with a set of three double dark slides, and that the lens is covered by a rotating ebonite shutter propelled by a steel spring, the tension of which is regulated by a lever operated from the bottom of the case. Indeed, the whole operative system as regards the placing of the shutter on whole or half cock, the discharging of the same by touching a button, the regulation of the rapidity of action, and the alteration of the focus (the normal adjustment of which is set for distant objects), is worked from below the outer case, and under such facile circumstances as not to necessitate the operator looking down when a shot is about to be made. A touch of the finger on the end of a lever cocks the lens shutter, by a similar touch it is discharged, no action of the hands which would excite notice being observed.

There are two finders: one on the top of the box for use when the plate is placed vertically, the other on the side for employment in the horizontal position. Each of these finders is composed of a lens, a diagonally placed mirror, and a tiny ground-glass, the ground-glass being brought nearly flush with the case and neatly covered with a sunk flap of leather, which, when raised, reveals on the ground-glass an image of the subject to which the camera is directed, which corresponds with that which would be flashed upon the sensitive plate by its own special lens were the trigger touched at that moment.

The lens, proper, is one of nearly six inches focus, and its normal position as regards the plate is such as to have every object, from extreme distance to those at a certain distance from the standpoint, sharply defined. But the back of the camera is provided with an adjustment, actuated by a lever—one of a focussing class of levers introduced by the Scovill Company several years ago—and by which a considerable movement of its end effects only a small movement of the camera back, being, in short, a species of “fine adjustment.” Its use may be briefly described in this way: When the lever is pushed as far as it will go in one direction, every object from extreme distance to beyond say, thirty feet, will be sharp. But if the object to be taken be within this latter distance, such as when a scene on the middle of a street is to be taken from the side pavement, one of two things will be necessary, either that a smaller stop shall be inserted into the lens so as to increase its depth of defining, or penetration, or then that the end of the adjusting lever shall be moved slightly towards the back of the camera, the precise distance being accurately determined by

certain marks or scratches made upon a plate on the bottom, graduated to suit any required distance. In this way objects situated within a few feet of the lens may be brought into perfectly sharp focus, even without the necessity being experienced of introducing a stop or diaphragm to give depth of definition.

When an instantaneous “shot” is to be taken at any object, the cabinet, which is being carried in the hand, is raised, and almost simultaneous with this movement, or prior to it by preference, the sliding safety cap of the lens is removed after “cocking” the exposur, the finder flap is lifted (all these operations being effected in two or three seconds), the finger placed on the exposing button, and the eye directed towards the finder. The object being seen in the centre of the finder, the button is pressed (which is accompanied by a faint click), and all is over. The dark slide is reversed for the next picture, the shutter is withdrawn, the lid closed, and the possessor of this tale-telling instrument moves unsuspectingly among his fellows ready for whatever next presents itself.

A ground-glass, with a peep hole behind, permits of the instrument being employed in the usual way when taking views, groups, or portraits other than those which fall in its way as a detective. To this end facilities are afforded for erecting it upon a stand.

The range in degrees of rapidity of action is very considerable. We have, when working the camera as a “detective” at its slowest, secured in the most perfect manner highly interesting scenes associated with the great fruit market in the vicinity of the office of this JOURNAL, all sharp and good; while we have also secured cabs rushing past in full speed to catch a departing train, or to deposit its living freight in time for the *matinée* at the Drury Lane Theatre nearly opposite, sombre although the atmosphere usually is in this portion of our great Metropolis.

Detective cameras although having their uses pretty fully developed in the United States—in New York in particular—have as yet had but a limited existence in this country, and all that we have seen have been of American inception, but we feel certain that before long they will be much more extensively employed. Their various applications, while too numerous to mention, will commend themselves to the reader.

THE STORAGE OF NEGATIVES.

THE best and most convenient method of storing negatives has always been one of opinion amongst photographers. To the amateur, who has only a hundred or two of negatives which he wishes to preserve, the case presents but little difficulty. A few grooved pine-wood boxes, each capable of holding fifty negatives, kept in a dry room, will fulfil all requirements. In these the negatives will be protected from the atmosphere, and if they and the boxes be numbered, any particular negative can easily be found when required. But with the professional photographer, who, perhaps, numbers his negatives by tens—or possibly by hundreds—of thousands, the problem is not so readily solved, and he who undertakes, as some do, to retain the negatives indefinitely, often finds his stock little less than a “white elephant.”

The principal conditions to be fulfilled when a large number of negatives have to be stored are these. The negatives should be so arranged that any individual one can be referred to without difficulty. They must occupy as little space as possible, and, above all, they must be well protected from

dust—which might result in scratches, moisture, and from atmospheric influences. For, notwithstanding that the negatives may be protected with varnish, moisture, as experience has proved, has more or less influence upon their stability if they be long exposed to its action. It is frequently said that gelatine are not so permanent as collodion negatives, hence they require greater care for their preservation. This, however, requires a certain degree of qualification. In collodion negatives the film is thin, and the image is very generally fixed with cyanide of potassium, which is much easier of removal than is the hyposulphite of soda. But even when hypo is employed with collodion a far less amount of washing is necessary for its removal than is the case with gelatine. But given the negatives, collodion and gelatine, with the hyposulphite thoroughly eliminated from each, there is no reason why the one should not be as permanent as the other, particularly if the gelatine one be treated with alum to render the film insoluble, provided, of course, no sulphuretting action has taken place in the fixing. However, it is not with the question of permanency that we are going to deal, but the most convenient and efficient method of storing the negatives.

For efficiency, nothing is much better than the grooved plate boxes. But when large numbers have to be dealt with, this system becomes expensive; and if, as is usually the case, the boxes are stacked one upon the other, it often entails considerable trouble to obtain any desired negative. Furthermore, when the plates have been badly cut, there is a difficulty in getting them in and out of the grooves. Grooved shelves, which at one time were largely used for storing the plates, are now seldom employed. Indeed, this is about the worst system that can possibly be adopted, inasmuch as the negatives are always exposed to the atmosphere, and any moisture it may contain, as well as to dust. Moreover, if the glass be badly cut, the same difficulty is met with as with the grooved boxes. Even if the plates are truly cut the weight of the glass in the upper shelves, pressing on the lower ones, often renders the negatives in them immovable.

Some photographers preserve their negatives by putting them up in parcels of twenty or so, with a piece of paper between each, and tying them round with string. This plan takes up but little space, and the negatives are well protected, but it is inconvenient when any particular one is wanted to obtain it, because a parcel has to be untied, the whole of the contents exposed, and then retied, the same operation having to be gone through when the negative is returned to its place. This trouble often leads to the package being left open, frequently for days, until the negative is done with, and this sometimes results in damage to the rest.

Many artists put each negative in a separate envelope, or into a paper bag, and store them in pigeon-hole shelves. This plan possesses many advantages; in fact, it is one of the best and most convenient that can be adopted. Each of the negatives is then well protected from dust, and when arranged in stacks, or piles, it is only the outside, or the topmost, one that has its envelope exposed to the atmosphere at all, except at the edges. Any individual negative can readily be obtained when required, and as easily returned to its place when finished with.

Here is a system we have seen in use for many years in some establishments. Each negative is neatly wrapped in a piece of glazed brown paper and numbered. The paper employed is the old-fashioned glazed brown of English manufacture, and not the material that is now often sold under the same name, of foreign make, which is of a far more porous character. The negatives,

in their paper covering, are stacked on shelves resting against the wall. The shelves have thin strips of wood fastened on the edges to prevent the plates from slipping off, and at intervals of half an inch, beyond the width of the negatives, are fixed narrow pieces of lath, to keep the different stacks apart from each other. A shelf of nine inches wide will hold about five dozen negatives in each stack.

There is a waterproof paper, resembling thin tracing paper, now in the market, apparently prepared with paraffine. It is employed by some manufacturers to pack dry plates in, and, extensively, by cheesemongers for parcelling butter and cheese. This paper, from its being waterproof, affords a safe protection to negatives from damp, and being thin occupies far less space than any other kind—particularly the glazed brown referred to. It is easily written upon, either with ink or a coloured pencil. Not the least advantage possessed by this paper is that, by reason of its translucency, the image can be distinctly seen without the trouble of having to open it. If the negatives be parcelled in this paper instead of the brown, a hundred can be stacked on a shelf of the width above given.

It is needless to say that the apartment in which the negatives—however well they may otherwise be protected—are stored, should be quite free from damp, and, by preference, it should be an inner room. If, however, this is not obtainable, an air space should always be left between the shelves and the outside wall. In no case should the negatives be allowed to rest against the outer wall of a house.

CONSIDERABLE interest attaches to certain recent exact experiments in regard to the atomic weight of gold, a question to which for years past some uncertainty has clung, owing to the exceeding instability of the various compounds of this metal. But by means of a compound of gold potassium and bromine Professor Thorpe and Mr. A. P. Laurie have been able to arrive at great certainty and exactitude in their calculations. The old atomic weight for gold was 197. Some later authorities (followed by us in our ALMANAC) have given 196, and now the above-named experimenters give us 197.28, if we take oxygen as 16; or if the now commonly accepted Stass value 15.96 be taken, that of gold becomes, according to Messrs. Thorpe and Laurie, 196.85.

IN our contemporary, the *Chemical News*, a complete series of the various specifications of the various patents in connection with the Auer von Welsbach incandescent gas light is given, and from them we learn that, contrary to the common idea, pure zirconium is not, even in the first patent, claimed as the sole material for placing in the flame to be rendered luminous. Herr Walsbach employs the oxides of both lanthanum and yttrium along with the zirconium oxide, and gives the best proportions to use, and also a proportion for the mixture of zirconia and lanthanum, without any yttrium. In his next patent he claims the use of thorium, and states that when used alone the hood is rigid, although the admixture of one part with two of magnesia is flexible when incandescent. He further gives details of the mode of giving various colours to the lights by means of varying the proportions in which these rare earths are mixed together. These being mostly in the range of non-actinic colours are of little interest to photography, and we therefore do not quote them, but in regard to a light of great brilliancy and whiteness, such as the inventor states to be produced by the use of a gauze composed of a mixture of the first three-named metals, there can be no doubt that it should be of the greatest value in portraiture if capable of production on a large scale. Electric lighting is of course unsurpassable, but it is entirely beyond the range of most photographers; an installation, however, of incandescent gas-burners giving a good actinic light might give photographic effect of value quite incommensurable with the modesty of its claims.

Those landscape artists who desire to obtain early spring effects should lose no time in securing them. The continued cold weather has caused a late spring and kept the leaves back, but the few warm days we have had of late has brought them forward, almost with a rush, and on some trees already they are showing signs of beginning to darken towards their summer tints. Judging from present aspects, what is known as spring foliage is likely to be of short duration this year. Just now some charming effects in landscape photography may be obtained which cannot be taken at any other period of the year. It often happens that it is impossible to obtain a good picture of many old country churches or buildings, owing to their being obscured by trees when the foliage is on, and if they be taken when the branches are bare the photograph always possesses a barren and wintry aspect. Such subjects can, however, be successfully taken before the foliage has acquired such proportions as to hide the structure, consequently the pictures so taken will, of course, possess a far more pleasing appearance than if the trees were devoid of foliage.

In the Patent Museum, South Kensington, is to be seen some interesting examples of early photography; they consist of some five or six dozen whole-plate portraits of scientific celebrities taken thirty or more years ago by the, then, firm of Maull & Polyblank—the first house, we believe, to publish celebrities. Although a very large proportion of the prototypes have long since been gathered to their fathers, the portraits still endure, and are in various states of preservation. Some appear to have undergone but little or no change, while others have become painfully yellow in the lights and half tints. But, notwithstanding this, the detail, even in the worst of them, is still there. A curious thing in connection with these pictures is that the ink, with which the names of the illustrious sitters are inscribed on the mounts, has, in many cases, proved less permanent than the photographs, it having changed to a pale, sickly yellow. It is to be regretted that these valuable portraits are not copied, and printed in a permanent process before they undergo further change. Every practical photographer is fully aware that photographs which have simply become yellow, as these have, copy much better than their appearance would lead many to imagine, and if orthochromatic plates were used, excellent reproductions, we are sure, could be obtained. It would, indeed, be a pity that these valuable portraits should be lost to the nation.

MANY would probably like to know how these photographs, which have endured so long, were produced, inasmuch as they were made at a time anterior to the introduction of the present method of alkaline toning. This we have ascertained from a reliable source. In the first place, the negatives were made with simply iodised, not bromo-iodised, collodion, and sensitised in a nearly neutral bath. They were developed with a solution of pyrogallie acid, restrained with acetic acid, and not with the iron developer now employed with wet collodion. The negatives, it may be mentioned, were made much more vigorous than is customary now. The prints are on albumenised paper, strongly salted—that is, according to present ideas—and sensitised on a correspondingly strong silver bath. The albumen used at that period was always diluted with water, consequently the surface of the prints is much less glossy than those on modern albumenised paper. For toning, the old compound toning and fixing bath—in which sulphur, no doubt, played an important part in the colouration—was used, while the washing was far less perfect than is usual at the present time. Notwithstanding this, these pictures, taken as a series, are in a far better state of preservation than are many which have been produced only during the past five or six years.

A NOTEWORTHY feature in connection with the above portraits is that they are all mounted on mounts embellished with bronze powder, and they appear to have suffered no injury therefrom. There are two gilt lines surrounding the portraits, and the name and address of the firm are also printed in the same material. In some instances it is difficult to see whether the imprint is in black ink or bronze, so much has it become discoloured. Clearly there is, or was, bronze powder and bronze powder, some of which has a fatally injurious action on photographs while others appear to be inert.

It would be interesting to know the number of cameras brought into use, by amateurs and professionals, on Saturday last, on the occasion of the Queen's visit to the East-End of London. At some points as many as half a dozen were to be seen at one time. It is rarely that such a favourable opportunity occurs for photographing a royal procession as that. The route was an unusually long one, and the light exceptionally good at the time. Some of the results obtained are really marvellous examples of instantaneous photography.

ONE of our daily contemporaries estimates the cost of the dresses worn by the ladies at Her Majesty's Drawing Room last week at something between sixty and seventy thousand pounds. It is not only the dressmakers and the milliners who profit by Drawing Rooms, as photographers come in for a large share of extra business on these occasions. As a rule, a very large proportion of the fair *débutantes* have their portraits taken in their Court dresses. Although a Drawing Room is always noted as a red letter day in the annals of West-End photographers, those held this year, we are informed, have brought them more business than formerly, this being attributed to the fact that it is "Jubilee year" and so many desiring to secure a memento of their introduction into society on that auspicious occasion.

COLOURED PHOTOGRAPHS.

RESPONDING to a request made by Mr. J. E. Mayall that we should witness a "private exhibition of my new process for producing highly finished coloured photographs without the aid of an artist," we went.

We are quite aware that some members of the general non-technical press have, in their ignorance of photography, designated this as something akin to the solution of the problem of taking photographs in their natural colours. But the colours, by whatever means they are prepared, or by whatever means they are applied (for the *modus operandi*, although patented, has not yet been divulged), have regard to the print itself rather than to the negative. This may be deduced from the title of the patent, "Printing and Colouring on specially prepared Porcelain or Paper; Silicon, &c., applied to secure Permanence;" and also from the following extract of a circular which was placed in our hands when visiting Mr. Mayall's studio, and which our readers are quite as able to interpret as we are:—

"The progress which has of late years been made in the methods of photography, and in the excellence of the work turned out, has undoubtedly been very great, and the photographer's calling has been transformed into a veritable fine art. Yet there is one thing missing to make the photograph really life-like and perfect, namely, a successful and thoroughly artistic process of colouring the same. The systems at present adopted are all purely mechanical and unscientific; and although many ingenious minds have of late devoted a great deal of study and time to the discovery of some improved process, these endeavours have until recently proved unsuccessful, and the defective method of mechanical colouring by means of the brush is still generally practised. It was reserved to a past master in the art of photography, who, at the same time, is an adept in chemistry, to solve the problem. Organic chemistry in its newest form is so little understood that it required a competent analyst, well up in the new methods of application both by the microscope and spectro-scope, like Mr. J. E. Mayall, the eminent and world-renowned photographer of 164, New Bond-street, to achieve success where so many had failed. Mr. Mayall, in fact, treated the matter on an entirely new basis. Starting with definite and well-matured scientific principles, Mr. Mayall has been able to lay a foundation of pure chemistry in every portion of the process, building up a complete process by the laws of affinity that renders the subsequent production permanent and indestructible. The new method of producing coloured photographs invented by Mr. Mayall is perfect and brilliant in every particular. The coloured photographs thus produced, in fact, resemble high works of art, surpassing them even in the higher quality of vitality, each work representing a living presence of the original. To these excellent features must be added the great advantage that climatic influences have no effect upon the work. The importance of Mr. Mayall's discovery can hardly be exaggerated. When once the splendid results of the new process will have become known, there will, no doubt, be a general demand for coloured photographs on Mayall's system. It is, therefore, no exaggeration to say that the invention will cause a veritable revolution in photography."

Our readers may inquire, "What appearance do these prints

possess?" We reply, that they very much resemble prints coloured by the well known "crystoleum," "Grecian," or "Egyptian" methods, only that there is no glass to which they are attached. Perhaps a better idea may be given of their appearance by saying they look as if a proof on albumenised paper had been washed over with a liquid pigment, such as a transparent coal-tar dye, that the "washing" had been performed by a broad brush or very small sponge while the surface was wet, that the finer touches had been put in by a brush (although one of the gentlemen interested in this invention says that a brush is not employed), and that when thus treated the whole is protected by a coating of either collodion or something else, which forms a thin film over the surface.

Now, as we have said, we are in entire ignorance of what this revolutionary process really is (and it is quite possible that our surmises are altogether wrong), but at any rate, from what we have said, our readers will be enabled to form some idea of what the coloured photographs look like.

We are told by those who assume to know, that the pigments employed are permanent, and that a process of liquefying silex, long ago discovered by Mr. Mayall, has something to do with it, and further, that immersion in sulphuric acid will not destroy these colours. This, we think, will remove the "new departure" from any suspicion of the aniline, or more correctly, coal-tar pigments having a place in the invention, which we are glad of, these having a very shady reputation for remaining immaculate for any length of time under a bright light. From atmospheric influences they can be readily protected.

We are sorry that Mr. Mayall, when inviting the press to see his specimens and learn all about the process, did not consider himself at liberty to afford any information as to the nature of his invention. It was surmised by one gentleman who saw the specimens, that it was a modified crystoleum process, the pigments being applied behind a pelicular positive made by one of the more permanent processes, and then backed up by paper. This may or may not be the case; we have no real idea as to how it is done, but shall learn all about it when the specification is published.

THE LATE "MAJOR" RUSSELL.

WITH sincere sorrow do we learn of the death of Colonel Russell, so well known to photographers of a former period as Major Russell. The sad event took place on Monday last, the 16th instant.

Photographers are more deeply indebted to Colonel Russell than many of them are aware. Quite apart from the able and skilful

investigations he made in connection with the tannin process and in preservative processes in general, and of the action of bromide of silver, he has made photographers his debtors for ever by giving them the alkaline developer and making them acquainted with the influence of bromide in the developer. He was a prolific contributor to photographic literature in former times, but during the last fourteen or fifteen years had resumed the more congenial life of a country gentleman of independent means on his estate of Stubbers, Essex.

He was born in 1820, and was a scion of a family settled in Essex for over two hundred years. His family name of Branfill—a name we are pleased to say not unknown in the photographic literature of the present time—was changed to that of Russell in obedience to the provisions of a will of the last of a neighbouring and nearly related branch of the Russell family.

He made many discoveries in photography, into which field he entered in 1856. It was in 1862 that he first published, in these pages, what has been termed "a matured and practical method of alkaline development," based on phenomena observed by Mr. Borda, of America, connected with the exposure of tannin plates to the vapour of ammonia.

His latest contribution to photographic literature is to be found in our ALMANAC for the current year, in which, at the special request of the Editor, he wrote a brief and succinct account of his discovery of the restraining action of bromide in the alkaline developer.

The portrait we give of Colonel Russell was engraved from a photograph taken of him by the late O. G. Rejlander.

ON THINGS IN GENERAL.

The Right to the Negative question has, as I anticipated, produced a plentiful crop of letters, exhibiting every shade of opinion and dogmatism; it has really been quite interesting reading. But, as I said before, it can be examined from two standpoints—the legal and the moral—and if these two had been kept separate, or, which would have been far better, the legal aspect left untouched, the opinions expressed would have had more value. What possible use is there in a layman giving his views as to the probable legal ruling in a case as to which even in its moral aspect such opposing views are held? The latter position can, it appears to me, be best shown by putting a query, "If the question as to the ownership of the negative were to be raised frequently between photographer and client, and had to be solved, what would be the probable charge for the negative the photographer would make? Would he not in some cases name a price that should be prohibitive, and in others make none at all?" No photographer of high standing and reputation, I venture to say, would part with his negatives. The copyright of a photograph is vested by Act of Parliament in the producer if he go through certain formalities. That seems to me the most conclusive point as to the morality of the matter.

Unfortunately the Copyright Act at present in force contains no stipulations as to publication of portraits against the sitter's will, and only the common law can be invoked in the endeavour to prevent such an abuse of the possession of a negative as is described by Dr. Thomson in the correspondence columns (April 22). Photographers who are gentlemen will scarcely be able to read the account he gives without blushing for shame of their *confreires*. There are, however, too unfortunately, a large number of *mauvais sujets* in the ranks of the profession, though it is daily taking a higher position.

The battle of the diaphragms is again being fought with a vigour almost approaching to rancour—all, it seems to me, very uselessly. It may be that the recently proposed unit may have theoretical, even practical, advantages, but what is the use of a standard being adopted at all, if, although the selection occupied considerable time and the careful thought of men of experience, it is to be upset in a few years in favour of one assumedly slightly better, to be in its turn, I presume, again set aside for a still more nearly perfect ideal? The truth lies in a nutshell; we have a standard which is adopted here and on the Continent; it works well, and is easily understood. Why should it be upset to make room for a more cumbersome one, whose only recommendation would be that it was easier to cut out fresh diaphragms by it, or to reckon the value of the few old unsystematic ones still in existence? The lenses sent out in recent years are mostly fitted with systematic diaphragms on the uniform standard, and it is

quite certain that any possessed by photographers before the establishment of a standard that are still untabulated would remain so even though the shade of Euclid should revisit the earth to describe a perfect standard. Speaking for myself, I prefer the exposure ratio to be expressed by the smallest possible number; and when I am out photographing I find myself comparing time of exposure by numbers which are simply multiples of a unit, which I give to the full aperture of one of my battery of (slow) lenses. Thus I have a case containing a number of lenses, the full aperture of each of which is $\frac{1}{4}$. I don't call that No. 16, and a stop of $\frac{1}{4}$ No. 256; I simply call the full aperture "1," and then I know that the $\frac{1}{4}$ being one-fourth the diameter is sixteen times as slow, and I mentally term it No. 16. With three or four cameras at work at once on different subjects, as I had on a recent occasion, the value of simplicity is very severely felt; and this I say, though I am considered rather an expert at quick mental calculations.

Leaving now all these disputed points, it is a pleasure to turn to calmer subjects, and such I find in Mr. W. H. Harrison's cogent remarks upon the preservation of astronomical photographs. It would indeed be a catastrophe if, after the vast collection of star plates that it is now decided upon making had been brought together, they should deteriorate before being utilised. It will be interesting to note whether, in the published proceedings of the Congress, any account will be found of precautions taken in this direction. (By-the-by as, according to the published accounts of the Congress, "the estimated cost for each observatory, including instruments, *extra assistants*, plates, measurements, &c., is about four thousand pounds," I am curious to know what is done with used-up assistants: are they added to the residues?) At the same time I am bound to say I think Mr. Harrison's views are far too sanguine in another direction, when, coupled with the exceedingly good advice that the photographer out of work should train himself in drawing and painting, he assumes that six months' practice with pencil and brush, combined with theoretical study of art, would give him a facility of touch that would enable him to "sketch with a bit of charcoal in a few minutes a background to suit the appearance and occupation of any particular sitter." The power of draughtsmanship is, fortunately for the artists, not so readily acquired as to make a man of much value after only six months' practice. All the same, the principle of the advice is, unquestionably, both sound and valuable.

In the same number of the JOURNAL I see some very false advice given. A writer, Mr. John Bartlett (quoted from an American source) states inferentially that the eyes take no part in the expression of a face, and he refers to Bell's *Anatomy of Expression* as an authority. I should also like him to name the page in that work where the face he describes is to be seen. Any one with experience in portraiture knows that much of the failure to please that is experienced lies in the imperfect rendering of the expression of the eyes—by "eyes," of course, being meant the whole of the orbit. Most members of the fair sex when being photographed open their eyes unusually wide—I suppose to make them look large—and the result is the expression is ruined; for the muscular changes thus produced are the exact opposite of those needed for a smiling expression or a near approach to it. A smiling mouth and amazed or terrified eyes are in nature incongruous, and to artistic perceptions horrible.

Mr. Pringle, as usual with what he takes in hand, gives us some capital advice, this time upon developers; but what does he mean when he says sodie sulphite requires careful neutralisation with acid? Unless a crude commercial quality be employed, the photographer may add four ounces to an ounce of pyro, yet utterly disregard its presence so far as its developing action on the plate is concerned. Sulphite alone added to "pyro" solution, I know, will develop a negative, but it will take an hour or two, and will not affect the plate so much as a variation of five per cent., more or less, in the quantity of ammonia ordinarily employed.

FREE LANCE.

ACCESSORIES OF THE LANTERN.

CHAPTER VII.—THE FITTINGS OF THE READING DESK.

WE may now pass under review some of the plans that are adopted for the illumination of the lecturer's desk. The amount of light required for such a limited surface is very small, the light of one candle

being sufficient. As white paper is an excellent reflector, and throws back a large proportion of the incident light, it is evident that if too strong a light were cast on the lecturer's manuscript during a lantern exhibition there would be an appreciable fogging of the image on the screen, which would be highly injurious in the case of changing "effects," views of statuary, and similar subjects. Hence the maximum light permissible in a desk lamp may be stated as being that of four candles; the weaker the light is, so long as there is enough to read by, the better does it answer our purpose.

The railway carriage reading lamp is used by many persons—it may be obtained of ironmongers at a cost of about six or eight shillings; the light is that of a short paraffine candle, which is inserted in a tube fitted with a spiral spring to force up the candle as fast as it burns. The flame is surrounded on three sides by a bright metal casing, the fourth side of which has a hinged reflecting flap. The casing does not confine the light completely, as a large portion escapes from the openings on each side of the flap; this can be prevented by soldering pieces of metal on the reflector so as to cover these openings. The tube being very short, only a four-inch candle can be inserted; there is thus great danger of the light going out before an exhibition is over, and unless the candle is of a hard composition and of a certain diameter it is very liable to be forced through the collar in a softened state by the pressure of the spiral spring, and the heat of the lantern acting on the exposed portion speedily melts it. The result is that the bright casing is filled with soot on the upper part and grease on the lower, the light goes out a few minutes after being lit, and the lamp cannot be put in action again without a thorough cleaning. On the whole, the railway carriage lamp, though no doubt excellent for its own particular vocation, is not well adapted for our reading desk.

Another article, obtainable from the ironmongers, is the bull's-eye, or dark lantern, the price of which is about half-a-crown. The light is that of a small lamp burning colza oil. The arrangements for shutting in the light are of an excellent character, the chief alterations the lantern requires being the removal of the condensing lens and the fixing of a tin flap in its place, so contrived as to shut in all light except that proceeding in a downward direction. The lamp should also have a small brass cap to screw over the wick tube, to prevent the oil escaping when travelling. The lantern will then give an excellent light for the desk. The revolving inner shutter, which makes the lantern a "dark" one, is useful, as by its means every ray of light can be cut off when effects are being exhibited.

Many persons find oil lamps dirty and troublesome to deal with—if the oil is thick, as it often is in cold weather, it is difficult to get the wick properly lighted, and unless the top of the lamp is kept quite clean there may be an unpleasant smell from the heated oil—hence a paraffine candle is often preferred to a lamp as being cleaner and giving less trouble in use. There is in the market a cone-shaped reflector made to rest by its own weight on the top of a composition candle; as the candle burns the cover descends, so that the flame is always central. The cover is silver-plated within, and green japanned without, and is sold at about six shillings. They are not well adapted for a reading desk, though frequently used for the purpose, as the light is insufficiently confined; they are also liable to get out of order by the air passages being choked up with grease.

Turning now to lamps specially designed for the lecturer's desk, we find that both candles and oil lamps are used. Of the two systems, the former is to be preferred if the lantern is made so that paraffine candles, of eight to the pound, may be inserted without the necessity of cutting them into halves. A plan that can be recommended is an arrangement similar to the railway carriage lamp; the candle is enclosed in a brass tube, on the upper end of which is screwed a brass collar, or ring, against which the candle is forced by the pressure of a spiral spring. The case surrounding the candle flame may be made on the model of the bull's-eye lantern, with the lens replaced by a reflector hinged at its upper edge. A bit of silvered glass may be fixed inside the reflector, at such an angle that the light will shine on the upper part of the desk. An important point is the attachment of the lantern to the candle tube; this must be arranged so that a current of cold air may surround the tube at the upper end, in order to prevent the candle being softened by the heat of the lantern. The upper end of the candle tube should be encircled by a tube two inches

ong and three-eighths of an inch larger than the inner tube, so as to leave an annular space through which air can freely pass. The lantern is attached to this outer tube.

Our lantern being now completed, we have next to fix it to the desk. This may be done by means of a small brass plate, which is soldered to the candle tube about four inches from the lower end, and is fastened by a thumbscrew to the middle of the raised part of the board. This will bring the candle flame to a height of about six inches above the desk, which will then be evenly lighted.

Section of reading desk and lantern.

We have now to add to our desk some appliance for signalling to the operator at the lantern. The method that seems to find most favour is the flash of red light, which is obtained very simply—by making a small hole in the lamp cover, so that the operator can see the candle flame. This hole may be half an inch in diameter, and is glazed with a bit of red glass. Outside the lamp there is a strip of sheet metal joined at one end; when the lecturer requires a change of view, he lifts up this strip with his finger, and allows the red light to shine forth for a moment, then, releasing the lever, it drops by its own weight and covers up the hole again. As this signal is a noiseless one, it does not interrupt the speaker in his discourse. The operator has, however, to keep on the watch for the light; if his attention is diverted by a lime falling to pieces, or a gas bag slipping out of place, the red light is unnoticed by him, and some other signal is then necessary. There may be fixed underneath the desk board a small bell gong, with a very light clapper attached to a weak spring; this is adjusted to give a faint “ting” just loud enough to be heard by the operator. The bell and flash of light together form a very efficient signalling apparatus.

There are, however, other and better means of communication between the lecturer and operator. In places where the optical lantern is a permanent fixture, an electric bell may be used. In the old London Polytechnic the lecturer had only to press a button and the change of view instantly followed; the bell was in the lantern room and had its gong replaced by a wooden disc, which was struck by the vibrating clapper—the noise thus made was inaudible to the audience.

Electric bells, however, are not desirable additions to a travelling outfit; the ordinary limelight apparatus is quite complicated enough, without having to lay down wires and put batteries in order. The system of signalling by means of “cues” does not require any appliances whatever, and is well adapted to impromptu speaking; it is, however, a system that requires a little practice to enable the full benefit to be realised. The plan is simply to indicate, or hint, by a few words in the discourse that a fresh view is required. I do not mean a call of “Now then, Mr. Jones, let us have the next picture, please,” but simple sentences or phrases, previously agreed upon, such as “Proceeding on our tour, we arrive at,” &c.; or, “Our next view will give you an idea of—;” or, “We now leave this district, and—.” If a portrait comes next the cue may be, “I shall now have the pleasure of introducing—;” or, “I am sure you will recognise—.”

By having half a dozen or more set phrases such as the above, and ringing the changes on them, the audience will not notice the signals, and that hane of many lantern exhibitions—the periodical break in the lecture, and the waiting for the operator to answer the monotonous clang of the bell—will be eliminated.

When an instantaneous effect or change of view is required, as in the representation on the screen of the firing of a Woolwich Infant, the cue should be a syllable. If the lecturer intends to imitate the report by means of a pistol, the words preceding the cue should be said slowly and evenly, thus, “The gun was—then—dis-charged.” While the last syllable is being spoken, the operator throws on the effect, and the speaker pulls the trigger—the two actions being simultaneous.

ALBERT WM. SCOTT.

SUNLIGHT.

A YEAR or two ago, when Professor Langley brought that delicate instrument for measuring solar and other radiations, his celebrated bolometer, to the Royal Institution, and gave a description thereof the work he had done with it, some surprise was felt that he did not exhibit the instrument at work, or do much more in the way of describing it than to call attention to a sectional drawing of the bolometer upon the wall. He made the mistake of under estimating the intellectual capacity of the auditory before him, and delivered a lecture more of an entertaining than a scientific nature. A few weeks ago, however, Professor A. W. Rücker, the successor of Dr. Guthrie at the Science and Art Department, South Kensington, gave a series of lectures at the Royal Institution upon *Molecular Forces*. Those lectures attracted an unusual amount of attention, because of the little known, except to specialists, scientific paths into which he led the listeners, and because of the way in which, with thorough knowledge of his subject, he laid bare the discoveries made in relation thereto down to the latest date. In one of those lectures Professor Rücker produced the bolometer, and stated that Professor Langley had tried to dissuade him from exhibiting it at work in public, because of the delicacy of the conditions required; indeed, Professor Langley had never tried himself to publicly exhibit it at work. The bolometer consists of a richly diaphragmed tube to check air currents, at the bottom of which tube are two groups of excessively thin iron or platinum wires. One of these sets of wires is screened from the action of the radiation under measurement. Professor Rücker, by the aid of a Wheatstone's bridge and a current of about one-tenth of an Ampere, measured the heat of a portion of the spectrum, obtaining, by means of a reflecting galvanometer, a sharp deflection several yards long of the spot of light upon the screen. Professor Langley, to check prolonged vibrations of the light needles of his galvanometers, has hit upon the ingenious device of obtaining air resistance by means of the wings of dragonflies instead of wings made of aluminium.

More recently, Captain Abney delivered a lecture at the Royal Institution, in the course of which he stated that Professor Langley a year previously had informed them that the sun would look blue if they could gaze upon it outside the atmosphere of the earth. Captain Abney added, with reason, that the sun under such conditions probably would not look so blue as Professor Langley expected, as excessively large additions of blue must be made to alter the appearance of strong white light. Accepting Professor Langley's own calculations, there would not be enough blueness to produce the anticipated effect. At the top of the Riffel, where the denser portions of the earth's atmosphere are below the observer, the sun does not look much bluer than when viewed from the lowlands.

In the course of this lecture Captain Abney gave the following figures as to the relative thicknesses of the earth's atmosphere through which the rays of the sun have to pass before they reach the earth, as the sun increases its distances from the zenith. The thickness at the zenith being called “one,” at fifty degrees from the zenith there is not much difference, and the thickness of atmosphere there may be represented by 1.5; at sixty degrees it is 1.9; at seventy, 2.9; at eighty, 5.5; at eighty-five, 10.2; and when the sun is in the horizon the relative thickness of atmosphere through which the rays pass is 35.5. I think the knowledge of these figures to be of photographic interest, because the more atmosphere the sun's light has to traverse, the more are the actinic rays suppressed in proportion to the others by the floating dirt in the air; this is why street gaslights look redder in a fog the more distant they are from the observer, as I have often pointed out in these pages. The figures also help to explain why as the afternoon wanes the light becomes weak for photographic purposes, while not much diminished in brilliancy to the eye; the difference in chemical intensity was still more marked in the old wet-plate days, for as plates increase in rapidity they usually increase somewhat in their orthochromatic efficiency.

In the present communication I am merely recording the work of others, and will conclude with extracts from my latest Royal Institution notes made but a few days ago, when Professor Dewar gave the

following information in the course of his present series of lectures of *The Chemistry of Organic Life*.

SOLAR RADIATION.

	Degrees Centigrade.
Top of Mont Blanc (Soret)	18.62
Limit of atmosphere	20.50
Limelight	0.40

The solar radiation is equal to fifty times that of lime at 2500°C. The absolute radiation of solar surface (Vielle) is 115,000 units of heat.

Light radiation, solar	72,000 candles.
" " electric arc	3140 "
" " limelight	120 "

RELATIVE LIGHT AND HEAT RADIATION.

	Light.	Heat.
Sun	30 per cent.	70 per cent.
Electric arc 10 "	"	90 "

In relation to the storing up of the energy of solar heat and light, by the leaves of plants liberating oxygen from the carbonic acid in the air, and storing up the carbon as one of the components of the starch cells, Professor Dewar said that man and his works does not give off sufficient carbonic acid to sustain all the vegetable life on the globe, and that most of the carbonic acid used by plants comes not from animals but from sea water, for that water is rich in bicarbonates which give off carbonic acid gas in proportion to the amount of pressure of that gas in the atmosphere. In illustration of the ease with which some bicarbonates are decomposed, he put some crystals of bicarbonate of potash at the bottom of some water in a test-tube; then he by means of the air-pump began to exhaust the air in the upper part of the tube; the more he took off the air pressure the faster did the crystals give off carbonic acid gas, which at last came off so freely that the water in the tube appeared to be boiling. He gave the following particulars as to the first work done by sunlight in the leaves of plants:—

FORMATION AND DECOMPOSITION OF CELLULOSE.

Carbonic acid.	Water.	Starch cellulose.	Oxygen.
6CO_2	$+ 5\text{H}_2\text{O}$	$= \text{C}_6\text{H}_{10}\text{O}_5$	$+ \text{O}_{15}$

One square metre of leaf surface produces 1.65 grammes of starch per hour, and absorbs in the process 4.68 units of heat. The total energy in the same time from solar radiation on the same area amounts to 622 units. The ratio of potential to available energy is 1 to 132. If the luminous portion of the spectrum be alone considered, the ratio is 1 to 33:—

Cellulose.	Water.	Marsh gas.	Carbonic acid.
$\text{C}_6\text{H}_{10}\text{O}_5$	$+ \text{H}_2\text{O}$	$= 3\text{CH}_4$	$+ 3\text{CO}_2$

Professor Dewar considered it to be remarkable that enough carbon is obtained from the trace of carbonic acid gas present in the atmosphere to build up the vegetation of the earth, but in some instances low pressure favours chemical action, and that may have something to do with the matter. In illustration of the principle, he took a glass flask coated inside with a film of phosphorus; this was non-luminous in the dark until he lowered the pressure of the air in the flask by means of the air-pump; the phosphorus then began to emit light.

W. H. HARRISON.

THE FASCINATIONS OF PHOTOGRAPHY.*

WE will now turn to the fascination offered by what may be termed "home portraiture." Here it is again very great, as nothing is more natural than that we should wish to preserve mementoes of those near and dear to us—"to secure the shadow ere the substance fade," as the poet says. How often do parents wish they had a portrait of the little one who has been taken away from them, or a child yearn for that of a dearly loved parent. The practice of home portraiture need not involve any expensive outlay in the way of a studio, &c., unless desired, as by the judicious use of a white screen (a sheet thrown over a clothes-horse will answer) and reflectors (such as a swing mirror) excellent portraits may be obtained in an ordinary room. Moreover, home portraiture enables us to gain a better knowledge of the laws of light and shade and the actinic power of the light, by which the relative exposures for the various rapidities of plates may be learned.

To those who can adopt or adapt a studio, a wide field of pleasurable results is open, as by its use character sketches or studies may be arranged and photographed in every conceivable style. We are also better able to regulate the light to our requirements, as it is evident

* Concluded from page 297.

that to obtain a portrait in the Rembrandt style the shadows will have to fall differently than for that of a full face. Again, suppose we are photographing a character group, entitled, we will say, "The Smugglers," the light will have to fall so as to throw long, deep shadows into the impromptu cave we have made from virgin cork, old stones, &c. To any one handy with hammer and saw a small studio need offer no very great obstacles in the way of its erection, and is a constant source of pleasure when done.

To those who have passed the rudimentary stage of photography, I would advise the study and practice of enlarging, either by day or artificial light, as by this means some of our choice "bits" may be made into beautiful works of art, the argentic bromide paper if properly developed giving that dull, matt appearance which is so much admired. After this comes platinotype and carbon printing, and for those engaged in the staple trade of this district, namely, pottery manufactory, I can conceive of nothing more likely to be of advantage and yield good results than the making of photographic enamels.

Photography has a great future before it. Already artists are using the camera as an aid to the brush, while its services to the military and scientific engineer are manifold. As a means of recording passing events we have only to look at the recent visit of the Queen to Birmingham, or of the unveiling of the statue of Mr. Campbell at Stoke. In this latter instance not only was an instantaneous picture of the ceremony taken, but had it not been for a few old photographs of the deceased gentleman, the sculptor would have had to depend entirely on a verbal description for his conception of the statue.

In furtherance of the ends of justice, photography plays a most important part, many a criminal having been identified by his portrait, and now that detective cameras are made the size and shape of a watch, or in such a form that they may be worn beneath the vest, this is all the more readily obtainable, as the person is not aware of being taken.

In the literary world, photo-lithography has established itself as a most valuable adjunct to book illustration. And, in short, the value of a knowledge of photography is so great that I think we have only to wait a few more years before seeing its principles and practice taught in our schools, not only as an art-science by itself, but as tending to inculcate an artistic conception, and to give a correct idea of the laws of light and shade.

In concluding with a few practical hints to beginners, I must ask the indulgence of the older hands for the benefit of those who are not already acquainted with them. In practising portraiture it is as well to remember that a light blue or white dress by coming out white in the finished print detracts from the beauty of the face and makes it appear darker. Also that the roseate hue of the healthy cheek always comes out darker than it appears to the naked eye.

By the same rule, too, blue eyes are difficult to take unless well screened from the direct light, so that they may get less exposure. On the contrary, dark eyes, or those well sunk into the orbits, require plenty of light. Very few people's noses are quite straight (don't look at each other, gentlemen), therefore, find which way the nose is bent—if to the right the sitter should look to the left, and *vice versa*. If the sitter has a long nose, a portrait nearly full face will be better than a profile; if it is *retroussé*, or, in plain English, "turned up," get the camera higher than the sitter's head and tilt it downwards slightly, or the same effect may be obtained, as regards the nose only, by the sitter leaning the head slightly downwards. It is not every one's fortune to have a "rose-bud" of a mouth, but as it is a most expressive part of the face, endeavour to so form the lips that they will have the expression desired. Above all things avoid a meaningless smile.

In taking views, endeavour to have the principal object in the middle distance, and remember that a prettier picture is oftener formed by placing the camera at an angle of view instead of square to the front. Practice thoroughly with one stop and lens first, and when you have mastered the working details of this do so with the other stops in succession. In developing extra rapid or sensitive plates, have an extra loose piece of ruby glass to place in front of that in the lamp, and remove as development proceeds. With the cheap plates in the market, do not be afraid of using too much pyro—in most of the formulæ given double the quantity may be used with safety, and this without the resulting prints being harsh or chalky. When choosing mounts select those which will harmonise with the colour of your prints—many otherwise good prints lose much of their beauty by the inharmonious contrast in the colour of the mounts.

Finally, endeavour to give your pictures the impress of character—even as the works of the great painters bear upon the face of them the evidences of the master hand that has wrought them. Be not

satisfied with mediocre work, but let your motto be "Excelsior," and I am sure then you will never regret having been fascinated with photography.

W. E. LEEK.

LEEDS PHOTOGRAPHIC SOCIETY'S CONVERSAZIONE.

THE first *conversazione* in connection with the Leeds Photographic Society was held in the Fine Art Gallery at the Municipal Buildings. Coffee was served at half-past seven o'clock, and the members of the Leeds Private Orchestral Society played a number of selections. A large number of visitors attended, for whose further entertainment, after an address by the President (Colonel T. W. Harding), there was an exhibition of lantern slides prepared from the works of members of the Society, and a display of photographs, chiefly from the same source. The Leeds Photographic Society, concerning whose history something was said during the evening, now numbers about seventy-five members. The number of works exhibited in two rooms placed at the disposal of the Society for the purpose by the Corporation is 575, these being mainly contributed by the amateur members of the institution. With regard to the exhibition as a whole it may without hesitation be pronounced exceedingly creditable, particularly for a first attempt. A hurried glance around the rooms reveals the fact that the amateurs have by no means confined their attention to one branch of the art they delight in, but have laid themselves out to acquire skill in it in every direction. The bulk of the works have their originals in beauty spots of natural scenery, and the operators whose tastes lie in this direction have found their own county marvellously rich in "subjects." Other amateurs, and these a goodly company, have brought the camera to bear for the purpose chiefly of producing architectural illustrations. To such as these the remains of Kirkstall have charms which are simply inexhaustible, and other historic ruins like Fountains, have with less frequency but equally good effect, come in for attention. The marine views form a highly interesting collection of photographs, and display some strikingly good work. One small room is occupied by photographs taken by one of the professional members, Mr. J. W. Ramsden. These are chiefly enlarged permanent portraits of well-known local persons, but in addition there are exhibited two photo-medallions, both curious and interesting. In producing these a photograph is first taken, and then by means of a bichromated gelatine a mould is made, from which a cast can be taken in wax or other suitable material. The President deserves well of the Society and of outsiders for the loan of a series of instantaneous photographs, which are remarkable in several ways. These works are of German origin, being taken by Herr Auschütz, of Lissa, and are analyses of the movements of men, horses, &c. Each series comprises something like a dozen photographs, taken at almost imperceptible intervals. Thus, such actions as those of a man throwing a heavy stone, a stork settling upon a nest, and a horse taking a fence, are illustrated at almost every second of their duration, and with an amount of distinctness and detail really surprising. Colonel Harding's collection also includes a number of interesting photographs of Eastern scenes. If for nothing else a frame of some half-dozen Daguerreotypes would be useful in order to compare with photography in the present day, but Mr. S. A. Warburton (Hon. Secretary of the Society) exhibits such a frame here which has another element of interest, inasmuch as it contains photographs of several former Mayors of Leeds who flourished nearly half a century ago. Another set of pictures of importance for purposes of comparison consists of some silver prints from negatives taken by the old process some thirty years ago, and acquired by the Society by gift from the late Mr. W. Sykes Ward. There is also a fine combination silver print by Mr. A. Fordsmith, entitled *Fortune Telling*, printed from no fewer than six negatives.

In the course of the evening the President gave all the friends assembled a hearty welcome, and trusted that they might consider that the exhibition repaid them for the toil of ascending to the lofty regions which did duty, more or less unsuccessfully, as the Art Gallery of the borough. He hoped that within twelve months they would possess a Fine Art Gallery in every respect worthy of the town, and very much more accessible than that in which they were assembled. Meanwhile they were grateful to the Town Council for placing at their service those rooms, such as they were, and they would show their gratitude by allowing the exhibition to remain open to the public for about a fortnight free of charge. The Society was not a new one. It was founded in the early days of photography. There was a tradition, and he believed it was a reliable one, that it existed in 1850, a very few years after the brilliant discoveries of Daguerre and Talbot made photography practicable. Mr. Teesdale, one of the Vice-Presidents; Mr. J. W. Ramsden, a large contributor to the exhibition; and Sir Percival Radcliffe, were original members, and still retained their connection with the Society. He did not mean, however, that the Society had been in continual operation; for years it was in a condition of suspended animation, but now it was a successful and useful institution. This exhibition would probably be accepted as a sign of vigorous life. The members were principally amateurs, and it was chiefly amateurs' work that hung on the walls. That work had been well done, and in some cases not only did the photographs show considerable technical skill, but very great artistic treatment. Having referred to the instantaneous photographs, forming, as it were, analyses of rapid motions, and to the lantern slides, he thanked the company for the interest they had

shown in a Society which was doing a modest but useful work in the cause of art, and which might well claim support if only because round one common centre of interest it brought together men filling very different positions in life.

SAVED BY A NEGATIVE.

THERE is not much romance in the life of a photographer, yet I can vouch for one romantic episode during my connection with that profession.

In the year 1863, I had a lucrative practice in the populous city of Liverpool, and in addition to an extensive studio connection I practised outdoor photography very largely. This outdoor work formed my relaxation from the monotony of the studio and dark room, although I must allow that the change from one description of this work to another was often startling in the extreme and sometimes even terrible.

For instance, one day I would be enjoying the fresh country air and the beauties of nature, while photographing some lordly mansion and park; the next, under orders from the Dale-street Detective Office, I would be obtaining a ghastly negative of some unknown victim of foul play, such as the corpse of the unfortunate man, found one morning behind a pile of timber at the Canada Dock, his throat cut from ear to ear. Any one who has had such work to undertake, will allow that the word "terrible" is the only one to use in describing the operation. One day I would be engaged at work on some lovely landscape, all the surroundings charming to the eye and soothing to the mind; the next, at the Princess Dock Dead House, securing the features of the suicide or the last victim by drowning in the Mersey. One day enjoying the sea breeze while photographing some noble vessel; the next, at the bedside of "somebody's darling," securing a last memento of the loved one ere the grave claimed its own. The latter was to me a most trying ordeal, as not only had I to face the dead, but also the distracted and grief-stricken relatives, whose anguish in some cases was pitiful in the extreme.

One memorable day in 1864, I was called upon at the studio by a gentleman whose mournful look and sombre attire at once told me his errand, and, as I anticipated, he required my services at a deathbed. In a few words he told me that a photograph was required of his only child, a little girl four years of age, who had just been called away to that "bourne from which no traveller returns." The gentleman, a Mr. Aubrey, was a Liverpool merchant, living in Abercromby-square. I sympathised with him in his trouble, for he appeared heart-broken at the loss he had sustained, and his strong, powerful frame seemed convulsed with agony as he told me how his wife and himself had made their only child their idol. He told me of its beauty, of its little winning ways, of the dark cloud arising when the little one was taken suddenly ill, of its unexpected flight from this world, and with bursting heart, he related how the dear one fell into her last slumber, calmly and gently, with the closing day. With the few words of comfort I was able to impart, he left me, on the understanding that I would be at his residence next morning.

On the following day, having packed the camera, stand, dark tent, and other requirements in a cab, I drove to Mr. Aubrey's house. Abercromby-square lies just outside the busy city, and contains the houses occupied by the *élite* of this great port. Fine, noble mansions form the four sides of the square, while the centre is laid out as a miniature park, forming a pleasant recreation ground for the inhabitants. I soon found Mr. Aubrey's house, which was really superb in its decorations. An air of luxury and refinement filled the rooms, and they contained all that wealth could lavish on them. Mr. Aubrey introduced me to his wife, whose fair features, now clouded by her great sorrow, brought strongly to my mind the fact that Death, the great leveller, brings anguish to rich and poor alike—none are exempt. Both Mr. and Mrs. Aubrey accompanied me to the death chamber, and there, in her last sleep, lay their only darling. He had called her beautiful, and this was no fatherly exaggeration. I wondered not at their great sorrow, to miss for ever the sight of such an angelic face, to be obliged to consign such beauty to the tomb, seemed hard and cruel. In all my experience of portraiture (and I have photographed hundreds of children) I never came across such a wealth of beauty, and I never saw such colour in the face of a corpse.

Left to myself, I proceeded to fix up my dark tent for the preparation of the plate and development. I must here, with the reader's consent, draw attention to the fact that twenty years ago the sensitive gelatine dry plate was not in existence. At that time the plate had to be prepared on the spot, used while wet from the silver bath, and developed immediately, which rendered a dark tent needful in every case. At present, thanks to the giant strides the "black art" has made, the plate can be taken ready prepared, is infinitely quicker than the old process, and can be developed at any time. Had the latter been in existence at the time of which I write, in all probability my "life's romance" would never have seen the light.

Again taking up the thread of my narrative, I will proceed to relate my further actions on this eventful day. After fixing up the dark tent, I mixed the developers and placed the camera on its stand, facing the bed. I then proceeded to place the body in the position best suited for securing the features, raising it slightly so as to obtain a good light on the face.

Returning to the camera, I focussed the features sharply on the ground-glass screen, and then having prepared the plate and placed it on the dark slide, I slipped it into the camera.

I must here point out that it was my invariable custom to obtain two separate photographs on one plate, in case one turned out a failure. This was easily accomplished by having the dark slide so constructed that one-half only of the plate was first exposed, then by pushing a portion of the slide sideways, the other half was next exposed, thus obtaining two distinct photographs of the same object on one plate. Having given the necessary exposure to each half of the plate, I returned to the dark tent and proceeded to develop. Dashing the developer over the plate, I watched the two images slowly emerging, and I saw at once that the features on the first half were coming out much sharper and clearer than those of the other; but my astonishment was great indeed when the development having been finished, I found on careful examination that while the features on one half were perfectly and sharply defined, those of the other half were blurred in a most extraordinary manner, the face being quite indistinct and out of focus. Like a flash it struck me that *the body must have moved* while the second exposure was being made, and another glance at the spoiled negative showed me that it was not a side movement of the face but a forward one, *towards the camera*, that had caused the blurring. In a moment I realised the astounding fact that *the head must have been raised*, and that life, however little, still existed.

Not a moment was to be lost, so quickly dashing the negative into the fixing solution, I left the tent and rang the bell. On a servant appearing, I ordered some hot water, and while waiting for this, I emptied the water out of my portable cistern, used for washing plates, and by the time this was done the servant reappeared with the hot water, which I quickly poured into the cistern. Telling the servant to proceed at once for a doctor, I placed the cistern to the feet of the child, and soon had the satisfaction of finding that the warm blood was coursing through the veins. Not long after the doctor arrived, and I briefly related to him the occurrences of the last few minutes. He grasped the situation at once, and thanks to his rare medical skill, I soon had the satisfaction of seeing the now restored child breathing once more, and with every hope of defeating death, on this occasion at least.

I will not enter into the medical aspect of the case, further than to state that the child's supposed death was, in the opinion of the faculty, a trance of the rarest description, seldom found out of Spain or Italy, and that my disturbing the body, combined with the strong odour of ammonia used in the developer, had broken the trance, and that, too, at precisely the proper moment. I shuddered to think of this narrow escape from premature burial, and I was overjoyed that I had been the indirect means of saving the little one's life, and bringing happiness to the sorrowful home.

J. L. II.

—Rare Bits.

["A little learning is a dangerous thing." The writer of the foregoing, who cannot possibly have any practical knowledge of wet plate photography, imagines that ammonia is an ingredient in the wet collodion developer. The youngest apprentice could have informed him to the contrary. The story, otherwise, is good, and we may add that, of course, the girl grew up and married the photographer who brought her to life by the pungent odours of the "ammonia" in his ferrous sulphate developer.—Eps.]

Our Editorial Table.

THE PRINCIPLES AND PRACTICE OF PHOTOGRAPHY, WET AND DRY.
By JAMES HUGHES.

THE fourteenth edition of this popular manual, revised and edited by J. Werge, has just been issued. It is refreshing to find that Mr. Werge has left a considerable portion of Mr. Hughes' original matter intact, for a more intelligent writer than Mr. Hughes never lived, and this renders the manual valuable, especially when superadded to Mr. Hughes' writings are those practical directions given by Mr. Werge, and by which the manual is brought up to the requirements of the present time.

WRAY'S CATALOGUE OF PHOTOGRAPHIC LENSES.

FROM this catalogue we perceive that Mr. Wray (North Hill, Highgate, N.) makes his rapid rectilinears with the nearly uniform aperture of $f/8$, with the exception of the smallest of that series, to which he gives the large opening represented by $f/5.6$, which should render this special instrument, the "back" focus of which is five and a quarter inches, specially valuable for instantaneous effects secured by drop-shutter or detective cameras. Mr. Wray has also still further developed his system of wide and narrow landscapes, of which it may be remembered we made favourable mention in our previous volume in connection with the abnormally large aperture at which they work.

CATALOGUE OF APPARATUS SOLD BY THE LONDON STEREOSCOPIC COMPANY.

WHAT with lenses, plates, and specialties of various makers, shutters, cameras, changing appliances, lanterns, and the other requisites in photography, not to speak of "sets" of apparatus, seemingly nicely put up in well-lit boxes (we judge so by the engravings), it would indeed be singular if one experienced any difficulty in becoming the owner of all that could be desired for practising the art after a perusal of this handsome catalogue.

BREAKING WAVES.

By J. A. MOORE.

THIS is one of the finest photographs of waves that we have seen. The negative, which, we understand, was taken in the neighbourhood of Scarborough, seems not alone fine in itself, but the artist has adopted the expedient of printing it in pigments of such a colour as vividly to aid the imagination in realising that it is the sea itself upon which we are gazing, and not a mere photograph.

Department for Inexperienced Photographers.

LENSES: CONJUGATE FOCI.

Nor even the most inexperienced photographer can have examined the image on the ground-glass of the camera without observing that when a distant object is in sharp focus a near one is not so, and *vice versa*; or if there be a small party in a garden, and one is seated at a distance of six feet, and another at ten times such distance, that a sharp focus of either of them is obtained at the expense of the other. Why is this?

If a camera be directed to an individual seated in front, the lens will form a miniature reversed image of such individual in the air. This image will not be seen unless the rays of light were intercepted at the focus by some diaphanous body, such as a small column of smoke, in the midst of which the figure would be seen in apparent solidity of a certain kind. If, instead of smoke, the image was received upon a sheet of ground-glass, it would be obvious that where this glass intersected any special portion of the image in air such part only would be seen depicted in the highest degree of sharpness.

What we are seeking here to establish is that there is a relation between the varying distances from the lens of objects in front of it and the corresponding parts of the image behind the lens. This relation is a conjugate one, and is known as conjugate focus. There are, therefore, two conjugates—the object in front of the lens, or *anterior conjugate*, and the point behind, in which the rays from such object cross, in which the ground-glass must be placed in order to see the image sharply, or the *posterior conjugate*. In proportion as the object in front is brought closer to the lens, so does the posterior conjugate, or, briefly, the focus, recede from it or become lengthened, so that in this relation a lens has no definitely fixed position of focus at all—this being dependent entirely upon the distance away of the anterior conjugate, or object that is being focussed.

A knowledge of the subject of conjugate foci is useful under many circumstances, more especially in copying. And in this connection we may say that if a picture is to be copied its own size, the anterior and posterior foci will be similar, and that *each* of these will be equal to the solar or equivalent focus of the lens doubled. Thus, for example, if a lens of ten inches is to be employed, that is, one which would produce a focus of a distant object at ten inches, by bringing the object—which in this case is the picture that is to be copied—sufficiently near to form on the ground-glass an image the size of the original, it will be found that this condition of equality of dimensions can only be secured when the object is twice the equivalent focus in front of the lens, and the ground-glass precisely the same distance behind it. Hence, to make a copy of a picture with a lens of ten inches focus, the distance between the focal centre of the lens and the ground-glass must be twenty inches, the picture being at a like distance in front. A copying camera to reproduce a transparency from a negative would, therefore, for such a lens, require to be forty inches in length.

It would only trouble the inexperienced reader were we at this stage to inform him of the rules by which conjugate foci are calculated, so we abstain from giving any of them at present.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 7035.—"An Improved Magnesium Light for Photographic Purposes." Complete specification. J. GAEDICKE and A. MUTHÉ.—*Dated May 13, 1887.*

No. 7121.—“Improvements in the Method of Focussing the Object Glasses of Cameras and in Apparatus therefor.” Communicated by L. M. Berthon. G. DOWNSING.—Dated May 16, 1887.

PATENTS COMPLETED.

AN IMPROVED CONSTRUCTION OF ROTARY ALBUM SUITABLE FOR PHOTOGRAPHS, MEMORANDA, AND THE LIKE.

No. 4178. THOMAS WILLIAM NAGINGTON, Stone-street, and WILLIAM HUGH WARING, 214, Wolverhampton-street, Dudley, Worcestershire.—March 19, 1887.

THIS invention relates to a certain improved construction of rotary album suitable for photographs, memoranda, and the like, and has for its object to manufacture such an article in a neat and convenient form and of any desired size, but we prefer to make it in miniature so that it may be carried in the pocket. The album is constructed in two parts, being preferably a pair of circular or polygonal plates of metal, wood, millboard, or other suitable material, pivoted together at the centre, and each capable of revolution; in one, but preferably in both plates, an aperture of suitable size for displaying a photograph, making memoranda, or other purposes, is formed.

The photographs or writing spaces are placed equidistant from each other on the internal faces of the plates, so that by moving the outer plate right or left around the centre, when two apertures are formed two different photographs or fresh spaces for notes may be discovered, one at either side.

The claim is: The hereinbefore-described construction of rotary album, consisting of a pair of plates pivoted together and adapted on rotation to discover photographs, writing spaces, or the like.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday, May 12, at the ordinary weekly meeting of the above Association, held at the Mascos Hall Tavern, City, London, Mr. A. Mackie presided.

Mr. J. TRAILL TAYLOR gave an account of the position of photography at the Newcastle Exhibition.

The CHAIRMAN called attention to a statement in the *Daily News* that in Donegal there is only one photographer to 206,000 inhabitants, and that the district is a poor one.

Mr. TAYLOR said that he and another member of their Association who had been to Antrim some years ago had seen no photographer there at all.

Mr. A. L. HENDERSON stated that a few years ago there was not one at Bray, a fashionable watering-place near Dublin.

Mr. F. W. COX had been experimenting in developing old platinum paper with washing soda, which he thought gave as good if not better pictures than the hot oxalate bath; there was no advantage in using cold oxalate of potash; he had tried his experiments on a piece of the paper kept in a desk for eight months. He also took a piece of platinum paper two months old, held it in the steam of boiling water, then dipped it in cold water, and dried it at the fire before he placed it in the printing frame, after which he obtained a fair print upon it.

Mr. C. HEINRICH TRINKS had recently seen Mr. Henderson photographing the stage at the Royal Aquarium by artificial light, under trying circumstances, and with about three and a half seconds' exposures, getting fair results.

Mr. HENDERSON believed the exposures to have been about seven seconds. He exhibited a new centrifugal separator for amateurs, one turn of the handle of which would give sixty revolutions to the basket.

The HON. SECRETARY remarked that, there being no such thing as "depth of focus," he should like to know the proper phrase to express what was meant.

Mr. TAYLOR replied "depth of definition." He had suggested at an American Convention that one of the most perfect lenses possible would be one in which the elements should be separable at the will of the operator; it might be mounted in a kind of telescopic tube.

The CHAIRMAN said that photographers ought to have more power of altering their lenses. Mr. Farnell had once published a method of flattening the field of any particular landscape lens at will.

A question was asked whether in any instance reflectors had an advantage over refractors for any photographic work other than astronomical.

Mr. TAYLOR responded that they in no case gave an advantage.

The meeting then broke up.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

A SPECIAL general meeting of the Association was held on the 5th instant to consider the proposed alteration of following rules:—Rule 4. Donors of one guinea and upwards shall be entitled to vote at general and special meetings, also at the election of pensioners, and shall further have the privilege of recommending for the consideration of the Committee cases of non-members, such as are defined as urgent in Rule 13. Rule 15 was altered to give the Committee power to act in such cases. Urgent cases are such as arise from

death, sudden illness, fire, or other unavoidable calamities; also when applicant has been out of employment for a length of time and requires aid to take a situation.

Mr. BEDFORD, in moving the resolution, said he thought this was a step in the right direction; donors would doubtless prefer that cases coming under their notice should be dealt with by an organized society, and would increase their interest in the Association; this would in no way interfere with the rights of members, but would give donors an opportunity of seeing that good work was being performed with their contributions to the funds. The Committee would still exercise its right to judge of each case upon its merits.

Mr. A. MACKIE seconded the proposition, which, after some discussion, was carried unanimously.

A committee meeting was then held. After the minutes of the previous meeting had been read and confirmed, Messrs. W. F. Benham, F. H. Carter, T. Sebastian Davis, and T. Newman were elected members.

A new handbill, briefly describing the objects of the Association, being now ready for circulation, the Committee desired to ask any feeling an interest in the work of benevolence to apply to the Secretary for a supply of the same, and aid them in their work by circulating them, and thereby bringing the Association under the notice of those who may not already know of its existence. The subscription being only two shillings and sixpence per annum every assistant should become a member.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

THE ordinary meeting of the above was held in the Free Public Library on Thursday evening, the 12th instant,—Mr. J. A. Forrest (President) in the chair.

Messrs. Thomas Comber, J.P., W. W. Rowley, Stewart Downs, and George Latimer, were elected as members.

Thornton's new patent camera was explained by the inventor. A tripod and shutter were also exhibited, the latter a modification of the Kershaw, but capable of giving time as well as exceedingly rapid exposures.

Pumphrey's card-mounted flexible glass films were exhibited in their various stages of the process, and the *modus operandi* of working explained by the SECRETARY (Mr. G. A. Carruthers). A number of various-sized negatives and prints therefrom met with much praise, and were pronounced fully equal to work done on ordinary plates, being free from granularity and in weight almost as light as paper.

Mr. Paul Lange showed an interesting series of platinotype views illustrating boat drill on board one of the Cunard Atlantic mail steamers whilst lying in the Mersey. This drill takes place on each vessel the day previous to sailing, and is well worth seeing; it only lasts five minutes, but during that time twelve excellent negatives were secured, paper and roller slide being of course used.

Mr. LANGE stated that he had made arrangements for a steamer which would be placed at the service of the members of the Liverpool and Birkenhead Societies at an early date for a day's cruise on the Mersey. The trip will be free to all who wish to participate, but each person going must come provided with camera and plates. June 18 was suggested as a likely day, that being the occasion of the Royal Mersey Yacht Club Regatta.

The PRESIDENT informed the members that an invitation had been received from Alderman Sammelson, of Liverpool, inviting them to his residence at Trefriw. It was felt that advantage should be taken of this kind offer by a visit there during an early holiday, Trefriw being one of the most picturesque spots in North Wales, and not inappropriately named the Welsh Garden of Eden, with numberless pretty Jenny Joneses to pose as Mother Eve.*

An excursion to Chester on the 7th instant was productive of some fine pictures, principally about the old abbey and on the Dee, Mr. Lange doing good work with his detective camera and producing many charming and quaint street views.

Mr. F. N. EATON, a newly-elected member, exhibited a half-plate camera of his own construction and design, with all the latest improvements, which, for an amateur, was an excellent piece of cabinet work.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the above Society was held at the Masonic Hall, Cooper-street, on Tuesday, May 10,—Vice-President, Mr. W. Stanley, in the chair.

The following ladies and gentlemen were elected members:—Mrs. A. Flower, Mrs. F. Farnivel, Mrs. J. Jones, Miss L. Farnivel, Mr. W. J. Bowden, Mr. H. E. Bythell, Mr. C. A. Davies, Mr. H. Duncan, Mr. E. Hinners, Mr. W. B. Kenyon, Mr. C. R. Lindsay, Mr. J. H. Taylor, Mr. J. Taylor, Mr. W. H. Tetlow, and Mr. Peter Woods.

A list of rambles for the season, arranged by the Council, was brought before the members, and the arrangements made by the leaders for this month's rambles announced. The list of places is as follows:—Worsley, Speke Hall, Millers Dale, Lymm, York, Chester, Alderley, Shrewsbury, Healey Dell, Dove Dale, Rostherne, Middlewood, Haddon Hall, Biddulph Grange, Ingletton, Hardcastle Crags, and Dunham Park.

The SECRETARY read a short paper on *The Society's Rambles*, mentioning the usefulness of these rambles as a source of photographic experience, and asking each and every member to study the list of rambles, and to try to make the rambles successful by personal attendance.

The LIBRARIAN announced further gifts of books to the library.

At the *conversazione* held after the meeting, Messrs. S. F. Flower, W. Greenwood, and J. R. Rose exhibited photographs of the triumphal arches erected during the Royal visit, and instantaneous photographs of the Royal party. Mr. J. H. Rigby exhibited a series of enlargements on Eastman's paper, 23×17 enlarged from full-plate negatives. The Secretary exhibited miscellaneous views; and Mr. W. Berry showed four prints from the one negative, each print being by a separate process, namely, one silver print, one

* What! In Eve's costume?—EES.

carbon print, one on Obernetter's chloride paper, and one on Eastman's bromide paper.

On Saturday the first outdoor ramble of the Society took place under the guidance of Mr. G. H. B. Wheeler, to Worsley, whence the party proceeded to Drywood Hall, a fine sample of the magpie style, remarkable for its fine overhanging porch. A good view of the front of the hall is easily taken from the lawn or tennis ground, and here the cameras to the number of thirty-five were soon at work. From here the party proceeded to the Warke Dam, where the members were allowed to use the private walks and drives. From the Dam the party went through the village of Worsley, where several views of the Court-house, &c., were taken. The day was fine, about fifty members and friends joined in the ramble, thirty-five cameras were used, and one hundred and ninety-four plates and films exposed.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society was held April 14, 1887.—The President, Mr. A. Coventry, in the chair.

The minutes of the previous meeting were read and confirmed.

The HON. SECRETARY, in compliance with a note handed to the President, read the rule relating to visitors, which stated that the same visitor could not be admitted more than twice in one session; but this rule did not apply to the popular meetings of the Lantern Section.

Mr. ABEL HEYWOOD, JUN., then read a paper, subject, *Odds-and-Ends*, and illustrated his communication by many stereoscopic pictures.

Mr. J. S. POLLITT then read a paper, subject, *On Stereoscopic Work* [this will appear in a future number], and he also illustrated his remarks by stereoscopic pictures and apparatus for making the same.

A discussion followed, and Mr. S. O'KELL described the method adopted by De la Rue in making his stereoscopic views of the Moon.

This was followed by a paper from the HON. SECRETARY (Mr. W. I. Chadwick), subjects, *Scarcity of Communications by the Members, and the Reason Why; On Outdoor Meetings; Presentation Prints; Professional and Amateur Photographic Societies; Encouragement to Young Members and Beginners in Photography; Grievances; SPEAK OUT*. He said as his communication was only intended for the members of the Society he did not think it desirable to publish it.

The above raised an animated discussion, in which Messrs. Mellor, Pollitt, and McKellen joined.

Mr. A. BROTHERS said he started as an amateur in photography many years ago with a cigar-box camera, &c.; he worked up and up until he became a professional, and was now an amateur again; and that during the whole course of his professional career he had always been most willing to impart all the knowledge he possessed to members of this Society except his secret processes, and that the photographic world was indebted to him for many "valuable ideas," amongst others, vignetting by tissue paper.

The HON. SECRETARY said his object had been attained; he thought the members required rousing up a bit at times.

Mr. Alan Garnett exhibited some prints and negatives on Eastman paper and the same subjects on glass.

The opinion of the meeting was, if the paper negatives were not so good as glass they were not far behind.

The last monthly meeting of the present session was held at 36, George-street, May 12, 1887.—The President, Mr. A. Coventry, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. William Russell was elected a member.

The PRESIDENT said he had great pleasure to call upon Mr. George Smith (Scientific Company, London), who had come from London by special invitation to talk to them on lenses and landscape photography.

Mr. SMITH commenced his remarks by a description of his long-focus camera, and explained the principle of the area system as devised by him to the masking of photographic lenses and diaphragms in order to ensure accurate exposure. The camera was for $4\frac{1}{2} \times 3\frac{1}{2}$ plates, with a range of focus of over twelve inches, and was provided with a set of five lenses, all working with one mount, in which they interchanged at either end by a bayonet catch, thus making five single lenses and four rectilinear, together nine different foci. The lecturer protested against the abuse of wide-angle lenses, adding that he himself never employed one of less than four-inch focus for a three-inch picture (lantern slide), and showed a photograph of horses ploughing, taken by a professional for sale, which was a most ludicrous example of the strained perspective of a wide-angle lens. He also showed, among numerous examples of the work done with this camera and lenses, some which, though charming "studies," were unsuitable for publication as views of the places they were supposed to represent.

The simplicity of manipulation of the apparatus and its thorough rigidity at all ranges was fully appreciated by the members, while the specimens of work done with it testified to its efficiency. The total weight of the complete kit, including camera, four double dark slides, lenses, case, and stand, was said to be under seven pounds.

Mr. SMITH then gave his views on the development of gelatino-bromide plates, instantaneous photography, &c.

A long discussion ensued, and various opinions were given.

Mr. H. GARSIDE said he used probably more pyrogallic acid than any member present, and for a long time it had been his practice to fill up the pyro bottle with water alone. It *did* discolour, but he never found any injurious effect from the discolouration. He used pyro and ammonia with bromide, and his negatives were nearly all fully developed in a quarter of a minute, certainly half a minute was the maximum time in his own work. If, however, he was developing a negative of which he had no idea of the exposure, he would take a little longer—say, perhaps, a few minutes.

Mr. POLLITT, in proposing a vote of thanks to Mr. Smith, said, with regard to developing, every photographer of experience had his own ideas, but with regard to what Mr. Smith had said about lenses, he was sure we had all heard

a most interesting lecture, and the area system of Mr. Smith's was so far in advance of many of our members that he felt sure it deserved their careful consideration.

Mr. MCKELLEN seconded the vote of thanks to Mr. Smith in very complimentary terms, and thus an instructive and entertaining evening was brought to a close.

DERBY PHOTOGRAPHIC SOCIETY.

THE members of this Society held their first outdoor excursion of the season on Saturday, May 7, when they assembled to the number of sixteen outside the General Post Office at half-past one p.m., and were conveyed by break to Dale Abbey, the route taken being (by the kind permission of Sir Henry Wilmot and W. Drury-Lowe, Esq.), through Chaddesden and Locko Parks. The weather was fine till just before reaching the Abbey, when it suddenly changed and commenced to rain. However, the party decided to make the best of it, and accordingly a large number of plates were exposed on the Church and Guest House, the Hermitage, and the east window of the Abbey, which is about the only portion remaining intact of this once fine old structure. At about five o'clock the sky cleared again, and the sun shining brightly caused those who had exposed their plates to wish they had waited. However, those of the more fortunate ones who had still some left made good use of the weather. At half-past five the party adjourned to the Guest House, where tea had been provided, and after a group had been taken they returned to Derby. At the Church Mr. R. Keene read an interesting description of the place, for which he was accorded a hearty vote of thanks.

LEEDS PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of the Society was held on Wednesday evening, April 6, at the Grand Restaurant, Boar-lane, Leeds.—Colonel Harding, the President, in the chair.

Upon this occasion the members met together, at the invitation of Colonel Harding, and partook of an excellent tea. After tea a vote of thanks to the President for his hospitality was proposed by Dr. JACOB, seconded by the Rev. A. STANDIDGE, and heartily carried.

The PRESIDENT then delivered his Presidential address as follows:—

I have thought perhaps it might be useful on this occasion to consider how far this beautiful invention of sun pictures has been useful to mankind, how far it is likely to be an important factor in the great educational work of the future. And, in the first place, let me deal with a secondary branch of the subject, and, as an amateur addressing a Society of dilettante photographers, say a few words on the advantages of cultivating a knowledge of this art as occupation for the leisure hours.

Among the subjects which a man may take up for his recreation few offer so healthy a pursuit or so varied an interest as the one which we are now considering. The development of amateur photography within the last few years has been remarkable, and I hope that the approaching exhibition which we are to hold in Leeds will reveal what excellent results in various directions can be obtained by mere amateurs.

The invention of rapid and reliable dry plates, the facility and the cheapness with which the necessary apparatus and materials can now be obtained, the ease with which modern light cameras can be carried on excursions, the simplicity and comparative cleanliness of modern processes, have removed the barriers which in the earlier days limited to a very few the practice of what was then not inaptly termed the Black Art. Without much expense of time or money, without the exercise of exceptional skill, most of us can attain, if not to a high degree of excellence in our productions, at least to such a level as enables us to add quite a new interest to our family life, and to open a new field for cultivating a love of the beautiful.

In the interest of those who are beginning work, I should like to point out how useful it is to keep prints in chronological order in albums. Of course not every negative is worth representing, and even the affectionate regard of every amateur for his own work cannot save some negatives from well-deserved destruction; but a print from every at all tolerable negative should be preserved, not in the inextricable confusion of a drawer full of curled-up prints, but by pasting it as soon as possible in the album, with a note of the date and any technical remarks as to exposure and condition of light as may appear desirable. Now, if the amateur is industrious in photographing himself, his wife, his children, his friends, his various surroundings, and especially if he travels much, these albums will become valuable volumes of pictorial biography and family history, full of delightful, if also sometimes of painful, interest, as children grow up to maturity, and loved faces pass away, recalling many scenes and circumstances which otherwise would be forgotten. Many a picture which at the time we thought little of, because it was a poor photograph, will be found after a few years to have quite other than technical interest. You will be surprised to find with what varied emotions you will look through some early volume, perhaps long laid by, in which, as you turn over its pages, you will see again the young wife and the baby, the children with the long-forgotten toys, and the once familiar friends strolling in the garden, or the simple arrangements of that first dwelling in which we remember having been so happy, or the jolly groups gathered together on that now distant birthday, or the simple portrait of some dear old man, not clad in the state garments and severe respectability of the professional picture, but just as we knew and loved him, sitting in the old arm-chair, with the well-worn dressing gown, and the spectacles, and the slippers, and the pipe, and the faithful dog not far away. For depicting and preserving such scenes as these the amateur will find his reward rather than in ambitious attempts to rival professional portraiture on a large scale and under conditions which are usually at great disadvantage compared with those of a studio. Indeed, the beginner will do well to exercise some caution in photographing his acquaintances. One incidental result may follow his attempts: he will probably attain to a better knowledge of the innate vanity of mankind, and realise the danger of letting our friends see themselves as others see them. The first condition of success for the professional is a knowledge of the art of successful flattery.

Landscapes, of course, offer a wide field for the amateur. The camera is useful in giving an inducement for health-giving rambles, and teaches him to delight not only in the sublime aspects of nature but in the sweet nooks where she hides away her modest beauties, whose simple loveliness will often be found the most suitable for photographic representation. And I think that our appreciation of the beauty of nature is assisted even by the deep disappointment which we often feel over our photographic results, a disappointment which enables us to realise how subtle is the influence of colour, and how, under certain conditions of atmosphere and light, even a commonplace landscape may become as it were transfigured with beauty, like the face of certain so-called plain persons under the influence of noble emotions.

Passing on, gentlemen, to the main question, it is well to bear in mind that photography, in its more practical form, is comparatively a new invention. It is only in recent years that its results have been largely felt, but what has been already accomplished will show us how important a part this invention is likely to play in the future education of mankind. The most noteworthy movement of the last hundred years has been that towards equalising the condition of men, towards enabling all men, as

far as practicable, to have an equal chance in the battle of life, by the removal of privilege, by equality before the law, and still more by bringing knowledge within the reach of all; for, as Professor Stuart lately reminded us, the *Great Leveler is Education*. Now, gentlemen, what are the chief avenues of knowledge? Are they not four? Personal experience, conversation, books, and the pictorial arts; the last three being the means by which we are enabled to benefit by the accumulated experience of those who have preceded us, and the constantly growing experience of our contemporaries.

It is in connection with what I may call pictorial education that photography plays, and will increasingly play, an important part. We are taught by pictures before we are taught by books, and pictures appeal more simply and more directly to the mind than do books. We all recognise this in the education of children, but we do not perhaps sufficiently appreciate how much we all learn, almost unconsciously, from pictures, and all the more readily that the primary object of most pictures is not so much to teach as to please.

We are already so far accustomed to the results of photography as not to realise at first sight how much we owe to it or how badly we should fare without it. Look at our book illustrations, and illustrated papers, and magazines. You will frequently find, even when the engraving is not acknowledged to be "from a photograph," that a photograph, nevertheless, has been the basis upon which the engraver has worked. Indeed, photography may be said to have rendered possible a large class of illustrated books and papers. Just as the invention of printing has enabled us to appropriate readily the knowledge of others, so the invention of photography has enabled us to see through other eyes than our own. To the modern traveller the camera is a sort of third eye, upon the retina of which he is able to receive permanent impressions which he can store for our use as much as his own. Before the days of photography it was rare for the traveller to be able to give a pictorial representation of the scenes which he witnessed, because, with the spirit of adventure which carried him on his difficult way, there was not often allied the skill to produce an interesting and useful sketch; or, possessing the skill, he had not the necessary time and opportunity. Thanks to the camera, however, we now all have within our reach an infinite number of pictures, giving us the most varied and valuable information as to the countries and people of the world; pictures possessing the scientific value of accuracy with a marvellous extent and delicacy of detail. For instance, at the recent Colonial Exhibition few objects were at once so interesting or so useful as the large and, for the most part, admirable collection of photographs in each department, which enabled us, by their faithful record, to realise in regard to each of our distant colonies the outward aspect of nature, the scenery of their mountains, and lakes, and rivers, and forests; the appearance of their towns, the aspect of their streets and monuments, the architecture of their public buildings, the degree of refinement or comfort of houses and furniture, the costumes and features of their people, with their modes of conveyance, their occupations, and amusements; their engineering work and art manufactures; the varieties of domestic and wild animals, or the luxuriance of the vegetation in the midst of which they dwell. And especially remarkable is the service of photography in architectural representation; for, in a moment, and at trifling cost, can be produced an architectural picture wonderful in its exactitude and infinite detail, reproducing not only what the traveller has seen, but much more than he could possibly have noticed, in, for instance, the wondrously complex beauty of a Cologne Cathedral or the profuse ornamentation of an Indian temple. So familiar, indeed, has photography made us with the great monuments of the world that the intelligent lingerer at home often knows more about them than the average traveller, and he is sometimes led to doubt whether he has not actually visited scenes which he knows so well. So there are many arm-chair travellers and fireside explorers, and, thanks to photography, the "untravelling traveller" may share in the breadth of view and the cosmopolitan knowledge of those who have the privilege of visiting other climes and distant peoples. Nor can we doubt that the multiplication of examples and details of the architectural beauties of strange lands has contributed to the widespread improvement of the public taste and aroused a new interest in the history of the people whose works of genius have won our admiration or wonder.

But the perfect fidelity of photographic representation could not fail to be useful in other directions, and, accordingly, we find it extensively used in commerce, where it provides remarkable facilities in prosecuting certain branches of trade. The next best thing to seeing a machine or a piece of furniture which we wish to buy is to see its photograph, on the truth of which we know we can rely. You are doubtless familiar with the value of photography in the large variety of trades connected with art manufactures and in the various branches of civil and mechanical engineering. In great works, such as the construction of ships and bridges, it not only furnishes us with accurate pictures of the completed structure, but enables permanent and correct records to be kept of various stages of progress, or exhibits temporary or accidental conditions, the knowledge of which is of great interest to the engineer. The applications of this art to commerce are rapidly extending, and one hears of it in unexpected directions, as, for instance, in the provision trade, where I find that certain American houses send out photographs from actual samples to show the different cuts in which they are prepared to supply bacon.

Passing on to deal very briefly with the application of photography to science, I may remind you that the camera has only to a very limited extent been as yet useful as an instrument of scientific research, although I believe it is destined in the future to do valuable service even in this direction. It differs in that respect from the microscope and the telescope, by whose discoveries "creation widens in man's view." We look out upon the vista of the infinitely great and the infinitely little, and realise that the work of the Creator is as admirable in the one direction as the other. The camera is less a discoverer than a spreader of knowledge; and just as it lets us see through the eyes of the wanderer in distant lands, so it enables us to look through those of the biologist at his microscopic studies or those of the astronomer as in the solitude of his observatory he gazes into the starry night. You all know how extensively photographs taken through the microscope are used in the illustration of scientific handbooks, and how by enlargement through the lantern on a screen they prove a useful factor in scientific and popular education. On the other hand, telescopic photographs are now common in connection with pictures of the moon's surface and transit or eclipse observations, and they have proved useful in determining doubtful points in relation to solar physics, while accurate and highly detailed star maps have been produced on photographic plates so sensitive as to record the existence of distant stars and nebulae the faint light from which fails to make any impression on the human eye.

Among the most interesting and promising scientific applications of photography may be mentioned Mr. Galton's researches into averages of physiognomy, and I should like to call the attention of members to some very curious and interesting composite portraits produced on the lines of Mr. Galton's suggestions, but on a new system, by Mr. John T. Stoddard, of which examples will be found in the March number of the *Century*. You will find there a true family portrait, a composite photograph which embodies in one typical face those of a father, mother, five sons, and one daughter. Mr. Stoddard also gives three composite portraits, the result and types of three school classes of young ladies, and, finally, what he calls a co-composite, in which those three composite portraits are merged into one, representing sixty-nine persons. These singular and even beautiful results are obtained by the successive exposure upon one photographic plate of a number of subjects, all of one size and in one position, full-face, three-quarters, or profile. All the faces are focussed so that the eyes and mouth correspond exactly to two horizontal lines and the nose to a vertical line upon a focussing glass, with the result that all the faces are, so far as their leading features are concerned, exactly superposed. The aggregate of the exposures equals the exposure which would be required under the same conditions of light to produce a full impression of any one subject, so that if the composite portrait is taken from twenty subjects the exposure of each subject is very short, equal to one-

twentieth only of the normal exposure. The pictures so produced are not blurred, as one might at first suppose, although they have a peculiar character of their own and a certain haziness of outline which adds rather than detracts from their beauty.

Turning to medicine and surgery, we find that they, too, are under obligations to the camera. Photography is much used in psychological medicine in depicting the physiognomy in different forms of insanity. It is employed by publishers in the delineation of diseased or injured conditions, while the lecturer on pathology is able by photo-microscopic slides enlarged upon a screen to demonstrate to a class of students the points of difference between sections from healthy and from diseased structures. Now, gentlemen, let us step across from the medical school to the police office. Here, too, the camera has become indispensable, and photographic albums are always at hand which have a very special interest for the detective police, since photography has become one of the safeguards of society against crime.

Where there is so much of accomplished fact to dwell upon it is rash, within the limits of a short address, to venture to refer to future possibilities; but it is not quite conceivable that instantaneous photography, which has made so much progress of late years, may yet prove a powerful weapon in the service of the police, and open a new chapter in the history of criminal evidence? If you look at instantaneous photographs of street scenes, or processions, or crowds, you will not fail to be struck by some unexpected features or to notice the evidential value which these pictures afford of the relative positions, the attitudes, the obvious intentions, of the many persons which they represent. In an instantaneous view which I took of an artillery detachment at work one luckless individual is for ever convicted of having at the moment been occupied in surreptitiously blowing his nose; while in another, of waves breaking on a rocky shore, I afterwards discovered an interesting couple, whom at the time I had not noticed, sitting very close to each other on a ledge far above, confident in their own happiness and the supposed absence of observation.

In Germany recently I was shown a new form of detective camera, rotary in action, and very flat in shape, for convenient suspension by a ribbon from the neck, so as to be concealed quite conveniently under the coat, with the small lens projecting through a button-hole. The apparatus once charged is capable of producing six instantaneous views in rapid succession by the simple pulling of a string. Whether this instrument will be so far perfected as to lead to our police being armed with photographic revolvers remains to be seen.

Among the best results in instantaneous photography with which I am acquainted are those which have been attained by a German photographer, Mr. Ottomar Anschütz, who has devoted himself to this branch of work, and whose pictures are of singular interest and merit. His enlarged views of the laying of the foundation stone of the new German Parliament House, and of the inauguration of the Niederwald Monument by the Emperor of Germany, are suggestive of the historical interest which must needs attach to work of this kind; and his collection of instantaneous photographs from recent autumn manoeuvres, taken by direction of the War Department, have aroused much interest in Germany. He has published a large variety of admirable examples of moving animals, and particularly of flying birds; but his most original and valuable contributions have been the serial photographs by which he has illustrated the analysis of muscular action, as, for instance, in the movements of a naked man taking a long jump, or throwing a stone, or of horses galloping, or leaping over obstacles. Others before him had obtained results very suggestive and interesting, illustrating the motion of animals, but they were characterised by an almost complete absence of detail, and were in fact little more than outlines or silhouettes. Those of Anschütz, on the other hand, notwithstanding excessively rapid exposures, are not only sharp but full of detail, and they have the scientific advantage of showing a consecutive series of views, following in succession at equal and very short intervals of time, so as, for example, to give a complete analysis of the movements of a horse in leaping over a hurdle, or of those of a bird in one flap of its wings during the act of flying. The difficulties to be encountered will be to some extent realised when you consider that the time required for the complete movements just referred to are about three-fourths of a second for that of the horse, and one-eighth of a second for that of the bird, and that the series of combined cameras must be capable of giving up to twenty-four successive pictures per second, at equal intervals of time. The series of ten views of a leaping horse, which I submit for your inspection to-night, have been taken with exposure of one-one-thousandth of a second, at equal intervals of time of one-sixteenth of a second. It is characteristic of the readiness with which the German Government encourages all educational works that it has assisted the photographer to the extent of over £1000 in the production of his complex and ingenious apparatus, and has instructed him to prepare for the military riding schools series exhibiting the analysis of the movements of horses at their various paces.

Gentlemen, I am anxious not to weary you with the general and, I fear, very imperfect review which I have undertaken to bring to your notice in this address, and therefore I will now only add a few words on a subject worthy of a more detailed consideration—the position of photography in relation to the arts. Let us consider it under the two aspects. First, as regards the original production of photography, and, second, in reference to photographic reproduction of fine art works.

We cannot claim for original photography that it can express the higher forms of art, for its very nature binds it too closely to objective as distinct from subjective expression. To many of the applications which we have hitherto considered, this characteristic was precisely what gave a value to photographic pictures. Then, the intention was to obtain accurate and reliable representations, as free as possible from the subjective modifications or exaggerations which the imagination or prejudice of the observer might impart to his picture. When, however (as in fine art work), the intention is to give pleasure by picturing the beautiful, the pure objectivity or realism of the photograph places it at a disadvantage. Original photography can show us indeed what the eye of the artist sees in nature, but it cannot express his lofty ideal, it cannot become a vehicle for the play of his fancy, or the inspiration of his genius; it belongs strictly to the realistic school. Nevertheless, the artistic photographer is able, by selecting for delineation such scenes or objects or conditions as harmonise with his own ideals, and by applying his knowledge of combination printing, to produce works of great beauty, which, in a certain reflex sense, bear the stamp of his own mind.

Any one who has compared views which different persons have brought from given districts, or even views by different persons of the same object, must become conscious of the difference between the mere photographer and the photographic artist. Therefore it is, that although original photography cannot express the highest forms of art, we owe to it a multitude of most beautiful pictures, which, quite beyond their value as mere realistic representations, and sometimes even in spite of it, possess for us a true artistic interest. We must note further that photography, like the arts of engraving and etching, is limited for its expression to monochrome; nor does the present condition of our knowledge warrant any prospect of our being able to pin the glory of colour, which we are able to bring as far as, but no further, than the focussing glass of our cameras.

But, notwithstanding these disadvantages, notwithstanding its bondage to realism and its inability to render the charm and variety of colour, photography has enriched us with a new source of delight in an endless diversity of pictures, where we may look now on the awful grandeur of the Alpine peaks clad in their mantle of eternal snow, or on the mountains mirrored in the placid waters of the lake, and now on the mighty plunge of the cataract, on the broad ship-laden river, or the babbling stream, that

"Gurgling kissed his pebbled shore."

Beautiful as are the views over land and sea and sky, the studies of trees and animals, which the camera has given us, its greatest service has been in the direction of portraiture.

The great portrait painters are few, and even these are singularly unequal, and

therefore before the days of the camera good portraits were rare indeed. For our grand work by a Velasquez, a Rembrandt, a Vandyke, a Reynolds, or a Gainsborough, we have thousands of mere daubs, whose wooden expression bears a more or less clumsy resemblance to their originals. Of the outward aspect of some of the most interesting figures of even modern history we can form but a vague idea. Our forefathers cultivated, indeed with some success, the art of miniature painting, and immediately before the advent of Daguerreotype there were skilful artists in black silhouettes, which still enable us to see dimly the profiles at least of our great-grandfathers and great-grandmothers. But the brilliant inventions of Niepce and Daguerre, and their successors, have enabled us to take, as it were, a short cut to the representations of the human face, which is at once the most interesting object in nature and at the same time the most subtle and difficult to portray in any other way.

Of course there are bad photographic portraits. Most portraits of any kind are bad! But where great technical skill has been allied to true artistic feeling, photography has endowed the modern world with superb portraits, in which hardly we see ourselves in the early days of simplicity and innocence, or recall with deep interest the features of those whom we have loved and lost, or in which we may draw near in a sort of intimate personal knowledge to all that the world knows of greatness, of goodness, of beauty, or of intellect.

We are warranted therefore in ascribing to photography, in regard to its original productions, an honourable place among the fine arts, and we may now proceed to consider very briefly the great educational service which photography is rendering in connection with the humble but most useful sphere of fine art reproductions. In this direction there has been a wonderful development in recent years, a development due in part to improvements in silver printing, and to the beauty and permanence of the results obtained by the carbon, platinotype, and other processes, and in part to the discovery of methods by which photography may be translated, so to speak, into printing in pigments or permanent inks, while recently photo-engraving has opened a wide field of valuable possibilities.

I have already referred to the service of photography in architectural representations. Sculpture, too, which, like architecture, relies for its effect upon beauty of form rather than charm of colour, is specially suited for the monochromatic rendering to which photography is limited. But among fine art reproductions it is in connection with copies of paintings and drawings that photography has met with its widest application.

Photographic copies of noteworthy modern pictures are available in Germany and France to a greater extent than in this country. By arrangement with the painters or the owners of pictures, photographs are published of all the more important works of the annual and permanent exhibitions, and thus the modern artist appeals to a widely extended public, and thousands are able to gather something of the charm or the lesson of a great work of art which they may never have the opportunity of seeing.

Not all pictures are capable of successful photographic representation; but the improvement of processes has given us admirable copies of a large range of works of art, including the masterpieces of the old and modern schools, and in such size as to be available for exhibition in public art galleries, where a selection of the productions of Messrs. Braun, of Dornach, or the Autotype Company, or the Berlin Photographic Company, or the Messrs. Goupil, and others, cannot fail to be of great value in the promotion of art culture. Copies of most of the best works in our own National Gallery, and in the great Continental collections, can now be had in excellent execution and at small cost; and these reproductions deserve to be more largely used than they are as prizes in schools, or for home decoration, when they are far preferable to inferior paintings of greatly larger cost. In these productions we have not, as in engraving or etching, the painter's work translated by another mind and hand, but copies of wonderful fidelity, in which the original may be said to have copied itself, and in which all that is characteristic is reproduced. For copies of works in monochrome, such as chalks or sepias, they may be printed in the exact colours of the original, reproducing the very texture of the paper, and with such perfection as to be only distinguishable from originals by the careful examination of experts.

Photo-engraving has, I believe, a great future before it, and dealing as it does with modern pictures, has the advantage of the co-operation of the artists themselves in the publication of their works. This beautiful art will, I think, to a great extent, supersede the old method of engraving and etching, although these will still be required to complete and give vigour to the photo-engraved plates. The variety of colour in which impressions may be taken by photo-lithography and photo-engraving, removes the reproach of monotony which has hitherto attached to collections of photographs, and any one who has seen the recent coloured productions of Messrs. Goupil & Co., of Paris, will have realised that a new charm has been added to photographic printing, and that new prospects of progress and usefulness are being developed. Indeed, when we remember that it is little more than forty years since Daguerreotype and Talbotype first became known, we cannot but wonder at the development and at the varied application of photography.

To the complete organization of the modern world, any new invention or discovery, any practical advance of knowledge, becomes rapidly absorbed into the universal system. On the other hand, it is remarkable how we seem sometimes to linger a long while on the thresholds of great discoveries. Some curious fact is recorded by the scientific observer, but lies dormant and unfruitful of useful consequences until possibly long after a comparatively small advance permits of practical application and unexpected developments.

We may look with respect, therefore, on abstract scientific research, although particular features of it may not at the moment appear to belong to what we consider useful knowledge.

Before the beginning of this century the action of light upon salts of silver had been observed, and the curious but evanescent sun pictures which Davy and Wedgwood had obtained, remained among the unapplied curiosities of science. Two generations passed away before the processes of Daguerre and Talbot, together with the discovery of hyposulphite of soda, and its action in dissolving silver salts, showed how sun pictures could be fixed and photography become practical. Even then the first steps were slow. Daguerre mentions that although landscapes required an exposure of seven to eight hours, he believed that single monuments, when strongly lighted by the sun, might be taken with an exposure of three hours only. The early portraits required an exposure of from three to ten minutes, while now negatives may be developed which have been exposed only one-one-thousandth part of a second! In our hasty survey we have seen how, once fairly launched, photography has grown to be a most valuable agent in the hands of man, how it has rendered vast services in the spread of knowledge, how it has assisted distant people to understand or know each other, how it has proved a great educational factor, given facilities to commerce, become a help to science, and a handmaid of art; how, too, it has provided us with one of those new sources of pleasure and interest, which go to compensate us for the life of keen competition and restless activity in the midst of which we moderns are called upon to work.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE last meeting of the session of the above Society was held on Friday last, the 13th instant, in the Royal College of Science, Dublin.—Mr. J. V. Robinson in the chair.

MR. LOUIS MELDON exhibited and explained a new form of washing trough for prints or plates as used in the Observatory at Stonyhurst. The trough was divided into two compartments and rocked on a horizontal axis, so that the supply tap was either over one or other of them. When one compartment was

full, the apparatus was so balanced that it tipped over, allowing the compartment just filled to empty, and placing the other one under the tap to be filled; and when the latter became full the same thing occurred, so that the compartments went on filling and emptying alternately.

A sum of money was voted by the Society for the expenses of the Triennial Photographic Exhibition which is to be held in the rooms of the Royal Hibernian Academy during the month of November next, and which, from the great interest taken in photography, and the increased number of workers during the last three years, should surpass its predecessor both in the number and quality of its exhibits.

Correspondence.

Correspondents should never write on both sides of the paper.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—Does a sitter sit for a negative and twelve *cartes-de-visite*, or twelve *cartes* alone? If he stipulates for the negative, then he must in law hold receipt for one negative and twelve *cartes-de-visite*.

If a party requires from me a negative of himself I charge, one negative, 1s.; one *carte*, 1s. A negative is not a portrait to deliver to a customer, and it must be stipulated if a purchase is arranged that the negative is of certain value. None but an idiot would demand the negative when not stipulated for. If I order my house painted at £4 15s., and then say I require paint-brushes, pieces of pumice stone, and all tools left after the job is done, I must, forsooth, be charged: To painting house, £4 15s.; to brushes, &c., used for doing the same, 5s. 6d.; total, £5 0s. 6d.

Now let us for one moment presume I order from Messrs. Marion 5000 *cartes-de-visite*, £2 10s. The receipt is for 5000. Can I demand the engraved plate? Certainly not, the agreement being for 5000 *cartes* at £2 10s. But Messrs. Marion hold the plate. Why do they do that? For the simple reason they would be pleased to supply more cards. But providing they invoice 5000 *cartes*, £2 10s.; the engraved plate, 10s.; total £3; then it is obvious I have paid for cards and the plate, and I can demand the same.

If a sitter be entitled to the negative, he is also equally entitled to your camera and lens, the latter being quite as essential to take the picture as the negative is in the hands of the printer. And, moreover, to make the whole thing more unmistakably clear, as I pay you three-pence per week for your valued JOURNAL, and the press you used being essential to your turning the paper out to me at that price, may I not respectfully ask you to send me on the press you use per luggage to Edge Hill?—I am, yours, &c.,

BLASE.

Liverpool.

N.B.—By-the-by, this reminds me of a swell calling here one day and asking in swellish terms whether I could take a negative of him. I replied, "Oh, certainly;" took him at his word, gave him a receipt—"Mr. Anderson, to one negative, 1s. Paid." When he called I duly handed him his negative. He looked at it all ways, and asked what the deuce was that, he was no nigger. Did I call that a portrait? I said, "Certainly not. You sat only for a negative and paid for the same. I did it, and here it is." After a little tall swearing I informed him that when parties sat for a negative they were handed what they had paid for, but if they sat for a *carte*, or *cartes*, it was specified on the receipt. Photographers do not give receipts for negatives and *cartes*. B.

To the Editors.

GENTLEMEN,—"J. F." need not be surprised at the silence of photographers on the subject he writes upon.

Photographers should know how to conduct their business best. The public go to them on their own terms; if those terms do not suit, they are at liberty to stay away. During more than twenty-five years' practice as a photographer I have never once had the negative demanded of me as a right. I have been requested to sell it, but often have I been desired to take great care of it. "J. F." does not seem to know that repeat orders form a large part of a photographer's income, and very often a negative years old yields an order for enlargement of from £5 to £20. That occurs frequently. "J. F.'s" suggestion to destroy the film would not do at all. A really good photograph is rarely secured a second time, and for that reason alone it should be preserved. Photographers know all about this, and go to great expense in fitting up rooms on purpose for the care of negatives, which means a good sum of money yearly in rent, some of our large firms requiring a building for this purpose alone. I give these few particulars, of which "J. F." seems to be quite ignorant or quietly ignores. I do not use argument, it is not necessary. I repeat, we do not charge for negatives, not even for the films (which is not his), and I think we shall still be allowed to conduct our business in our own way. We have nothing to do with either engraver's plates, lithographer's stones, or type pie.—I am, yours, &c.,

I, Orchard-street, Sheffield, May 9, 1887.

FREDERICK BASSE.

To the Editors.

GENTLEMEN,—Permit me to express my opinion with regard to "The Right to the Negative." First, then, my opinion is that the negative

belongs by right of custom to the photographer. In proof of this statement it will be found that when any dispute arises in business matters in regard to *unwritten laws*, if taken into court, judgment will be given in accordance with the custom in vogue in that particular business.

I am not aware of any law entitling the "sitter" to the negative, and it is quite notorious that the custom among photographers has been, and is, to claim the negative.

Although an extra charge is made for taking the negative, I fail to see how it should become the property of the "sitter," who only pays for the skill, labour, plate, chemicals, camera, lens, studio, &c. Query: Should the whole concern belong to any one who pays for the production of a photograph? Hardly!

Also some of your correspondents advise the destruction of the negative. But who is to be the destroyer? The ownership must be decided first.—I am, yours, &c., N. S. B.

Kirkcaldy, May 16, 1887.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the Editors.

GENTLEMEN,—May I trespass upon your kindness to insert this notice. The Committee are desirous of extending the knowledge of the existence and objects of the Association, and to further that aim have issued the enclosed handbill. I shall be pleased to forward a supply to any photographer, photographic dealer, or others willing to assist in the circulation of the same, who will, by this action, render material assistance in obtaining the requisite publicity.

With the subscription only 2s. 6d. per annum, every assistant should become a member of the Association.—I am, yours, &c.,

Offices: 181, Aldersgate-street, E.C., May 16, 1887. H. HARLAND.

THEATRICAL PHOTOGRAPHS.

To the Editors.

GENTLEMEN,—I confess I am somewhat surprised that Mr. J. F. Roberts took the trouble in last week's JOURNAL to say that I followed *his* example in taking theatrical photographs; but having done so, I am quite sure he will gratify me by taking a very little more trouble and answering the following plain questions:—

1. Who proposed and proved to him that such photographs could easily be taken with orthochromatic plates, and persuaded him to see Wyndham on the subject? 2. Who went with him and took negatives of the stage, without figures, in order that future exposures should be correct? 3. Who gave him the formulae for orthochromatising his plates, and explained how it was done? 4. Who was it that, after all arrangements had been made for the joint photographing of *David Garrick*, wrote a letter, received on the morning of the day of performance, saying that Mr. Hyslop could not be admitted, as it was merely a private matter, and Mr. Wyndham objected to being photographed by any one but Mr. Roberts?

There is just one point more in Mr. Roberts's correction I would like to notice, and that is his grievance against the Camera Club because some one did not call attention to his pictures. I am not aware whether any mention was made or was not made of the pictures, but I think that Mr. Roberts might (at least in the first instance) have brought his grievance before the Club, through the proper channels, before airing his wrongs in a public print.—I am, yours, &c., Wm. H. HYSLOP.

Camera Club, May 17, 1887.

Exchange Column.

Will exchange a Victoria camera and four lenses for interior backgrounds.—Address, G. SPRINGTHORPE, 18, Tackett-street, Ipswich.

Will exchange a Lerchour's single lens, fourteen-inch focus, for a whole-plate zinc negative washing trough.—Address, R. DAVIES, 5, Sunningfields-crescent, Hendon.

A nearly new copying press, size about 12x10, in exchange for a Marion's large developing lamp.—Address, A. WOODWARD, 12, Alfred-street, Blackpool, Lancashire.

I will exchange a fifty-two-inch Coventry tricycle, suitable for carrying photographic apparatus, for Ross' Universal or symmetrical whole-plate lens, or good accessories.—Address, W. PLAYLE, Bishop's Stortford.

I will exchange the following for 12x10 studio camera with two slides:—Quarter-plate Lancaster pocket camera, one double slide and lens, 5x4 Ross' view ditto, five Victoria portrait lenses fitted to plate, and cabinet burnisher.—Address, MYLES GARNER, 298, Holloway-road, N.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

J. H. Mann, Sandall, near Doncaster.—*Interior views of Bolton Castle.*
John Owen, Newtown, North Wales.—*Portraits of the late Mr. Ceiriog Hughes.*

E. BONSFIELD.—Received. In our next.

F. W. B.—It is a printer's error. It should be *ferrous* sulphate, not ferrie sulphate.

R. C. STOKES.—The surface of the silver vase may be dulled by the well-known expedient of placing a piece of ice in it. So it also may by dabbing it over with a piece of glazier's putty.

C. C. C.—The pictures in question are by the collotype process. They are about the best examples of collotype we have seen for a long time. They are returned by post, as desired.

O. X.—You have continued the heat too long. As soon as the solution becomes concentrated set it aside to cool; crystals will then form. The silver had better be crystallised before use.

E. J. W. will feel obliged if Mr. E. H. Jaques, who read a paper before the Birmingham Photographic Society, will read the formula given on page 254 and say if the proportions there given are correct.

CAMO.—Print the pictures on albumenised paper and tone to a cold colour then dye them a pale greenish blue with Judson's dyes very much diluted. The numbers may be written with a pen charged with liquid Chinese white.

A. W. MIDDLETON.—The chief faults in all the negatives sent is under exposure. Some of the plates require quite three times what they received. With this information we advise you to try the subjects once more. Good pictures of similar subjects are being constantly taken.

SAML. WILLS wishes to know how he can blacken a camera stand which he has constructed of pine. The wood can be blackened by painting it with a mixture of brown-hard varnish diluted with about an equal part of methylated spirit, to which some lampblack has been added.

H. R. W. writes: "I have an old but good quarter-plate portrait combination lens; would you kindly tell me if it requires any alteration to make it suitable for enlarging, and if so, what?"—The lens require no alteration, and if it be a good one will answer quite well. Of course the posterior glass must be placed next the negative to be enlarged.

TYRO says: "I have seen that in your JOURNAL you recommend shellac varnish for wooden washing trays. I wish to make a large tray, 16x14x8, and wish to preserve the wood and make watertight, so as to wash prints in it. Will you kindly inform me if shellac varnish is best for above, and how to make the varnish?"—Shellac will do quite well, but the first coating should be with a dilute solution, so as to allow of its being absorbed by the wood. The after coatings may be thicker. The shellac solution is made by dissolving the lac in methylated spirit. Brunswick black also makes a good water-proof coating for wooden vessels, and is preferred by many to shellac.

GREENHORNE writes: "How is it, that when I focus my single lens with a large stop (say three-quarters of an inch) I can fill a 7x7½ focussing screen with the view, but after putting in the quarter of an inch stop to make it sharp, I can't fill a 6½x4½ plate to the edge, but get a circular picture. I am taking a rather dark interior, and I can't get a sharp picture unless I put in the quarter of an inch stop, but that reduces the picture. How can I alter this, as I want to take the whole of the interior? My lenses are only about six-inch focus, and the church is about ninety to one hundred feet long."—Our correspondent's trouble arises from the stop being placed too far from the lens. If the stop be placed nearer none of the view will be cut off.

S. TALLOW asks: "Would you kindly inform me in your JOURNAL what is the cause of my silver bath becoming crowded with crystals like short hairs, rendering filtration necessary nearly every day. I have looked up Abney's work on the subject, and the only thing I see like the defect is over iodising, which he says causes these crystals or granules; but I have made up a new bath and put no iodine in it, and the same thing occurs after a week's use."—The needle-like crystals are caused by the bath becoming supersaturated with iodide of silver. All baths are liable to this, even after continual use. The remedy is to add an equal quantity of water to the bath, which will precipitate most of the iodide, filter, and then make up to the original strength with nitrate of silver. Very little reliable information has been published on the production of blocks in half tones.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—There will be an excursion on Saturday, May 21, to Waltham. The train leaves Liverpool-street (Great Eastern Railway) at forty-three minutes past two p.m.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, May 25, 1887, will be on *Photographing Interiors*. Saturday outing at Winchmore Hill. Meeting at Railway Station as near two o'clock as possible.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The usual monthly technical meeting of this Society will take place on Tuesday next, May 24, at eight p.m., at the Gallery, 5A, Pall Mall East, when a demonstration will be given of *Platinotype Printing*.

EFFECT OF TOBACCO ON THE SIGHT.—On the occasion of a lecture on lenses and cognate topics by Mr. Traill Taylor at the Balloon Society, Royal Aquarium, on Friday last week, it was stated that astigmatism, or the inability to see vertical and horizontal lines with equal distinctness, could be temporarily induced by tobacco, the eye resuming its normal functions in about an hour after the pipe was laid aside. Dr. Lindsay Johnson afterwards corroborated the statement as to the effect of tobacco on the sight by giving an instance of colour blindness having been produced by its agency. In course of his lecture Mr. Taylor gave some statistics relative to the enormous heating power of the sun's rays when concentrated by lenses or reflected by mirrors. By the former, such refractory metals as platinum could be melted in a few seconds; while, by the latter, it would not be difficult to ignite any wooden structure at a distance of half a mile or more.

No. 1412. VOL. XXXIV.—MAY 27, 1887.

VIGNETTING FACILITIES.

NUMEROUS are the devices which have been created in the brain of the ingenious photographer in order to adapt his vignetting mask to the negative while in the printing frame, and not a few patents have been obtained for mechanical appliances to facilitate this end. Of these, some have been so elaborate as to render their possession a matter involving an expenditure which might in some slight measure hamper the financial resources of the young photographic aspirant. Without detracting from the special merits of the various vignetting arrangements which have existed or do exist at present, we are in a position to describe one which possesses merits peculiarly its own, being simple, cheap, and very readily adapted to the negative. It owes its existence to Mr. Lyonel Clark, C.E.

Every one is aware of the system of vignetting by placing in front of the negative a piece of cardboard having in it a suitable aperture. Mr. Clark's improvement upon this is one which very little reflection will show to be of great importance. It consists in substituting for the cardboard a sheet of thin lead; that which Mr. Clark left with us is what is known as "four-ounce" lead, and is therefore exceedingly thin and, consequently, cheap. It is manufactured mainly for the purpose of lining damp walls upon which paper is intended afterwards to be hung.

Having obtained a piece of this lead somewhat larger than the printing frame (this is important), cut out the oval or other desired form of opening, a pair of light scissors sufficing for this purpose, for it cuts quite as easily as the thinnest paper, if not somewhat easier. Laying this opening down upon the figure in the negative that is to be vignettied, and having adjusted it carefully, the margins of the sheet lead are then bent over the edges of the printing frame, by which the mask is permanently retained in position. Owing to the extreme pliancy of the lead it may be lifted up from the negative to any desired extent, so as to give the maximum of softness to the margins of the portrait, or, if desired, it may be raised irregularly, so as to produce any effect as regards softness of outline demanded by artistic requirements.

Unlike a paper or card mask, this is unaffected by rain or the weather, and when done with the margins are raised and the sheet of lead is ready to be fitted on any other portrait. For large portraits it may be desirable to employ a somewhat thicker sheet than that mentioned.

It is evident that by preparing and keeping in stock a few sheets of the class here described, with apertures of different forms or dimensions, the photographer will possess a vignetting armoury which will serve him in good stead and be always ready for use under all circumstances.

Small although this invention may at first sight seem to be, yet is it one which is capable of greatly facilitating the production of vignettes.

PHOTOCHLORIDE OF SILVER.

WERE it asked, Who of all those connected with photographic science has, by original research, careful experiment, and lucid description, done most to advance our art in what we may term its practical science? it is probable that the answer would be M. Carey Lea, of Philadelphia. Those who have access to our volume for 1875, and who will turn to the issue for May 28, will find there such a record, albeit an imperfect one, of the contributions of this eminent *savant* and *confrère* to chemistry, photo-chemistry, and practical photography, as will prove almost astounding, and yet at that period his work was still going on. Compelled by a tedious course of ill-health to discontinue his regular communications to THE BRITISH JOURNAL OF PHOTOGRAPHY, of which he was for many years the honoured American correspondent, he has of late been engaged in an investigation in the subchloride and "photochloride" of silver, in a large measure, in connection with heliochromy.

Although for the last two or three years the photographic world has heard but little of Carey Lea, yet when we study the paper which appears in our columns containing the result, or rather a part of the result, of his work during this time, we shall see that it was such as to call for his undivided attention. Mr. Lea believes that he has been able to prepare by chemical means the material forming the famous "latent" image; and he has confirmed his results by a great number of experiments. It appears to consist of a sort of molecular combination between chloride of silver (Ag Cl) and subchloride of silver ($\text{Ag}_2 \text{Cl}$)—the amount of the latter substance varying from an extremely small proportion up to eight or nine per cent.

It is difficult, or impossible, to explain according to chemical theories the nature of this combination between the chloride and the subchloride, but it is evidently of a remarkable and surprisingly stable nature, for reagents, such as strong nitric acid, which would attack either of these bodies separately, has no effect upon them when in combination. For this compound or double chloride Mr. Lea proposes the name of the "photochloride," a term which is not, we fear, in accordance with the rules of chemical nomenclature, but which has the advantage of avoiding any theory as to the exact composition of the substance.

By forming or spreading this "photochloride" upon the surface of paper, &c., Mr. Lea has been able to obtain coloured copies of the spectrum, and of paintings on glass, &c.; and we

agree with him that this photochloride which he has been the first to identify, to isolate, and to prepare in quantity, is the same as that with which Becquerel, Poitevin, and others obtained the promising results in heliochromy recently described by Jerome Harrison in our pages.

In a continuation of his paper next month Mr. Lea promises to deal with the manner in which the latent image is produced by the action of light.

We hail with delight Mr. Lea's reappearance in this connection.

PHOTOGRAPHING FLOWERS.

BEFORE leaving the subject of lighting, it may be well to point out that a very great deal may be done to improve the effect by arranging the position of the object with regard to the window or source of light so as to best suit the character of the subject. Thus, if a spray or branch have a natural inclination in a certain direction, the heavier shadow will be cast on that side to which it leans, and it will be proper to so adjust the light that that side be not thrown into too great darkness. Or, again, if the subject be furnished with bushy foliage, with prominently projecting branches or sprays, the hollows or depressions will, if lighted wholly from the side, be rendered as black, unsightly patches, whatever length of exposure may be given. In such cases the best course to adopt is to light more or less from the front by bringing the camera nearer to the window and removing the object further away, but more in the direction of a right line from the centre of the light. In this manner, and in many other cases, much trouble and disappointment is saved, for when the lighting is not managed to advantage the difficulties always present in exposure and development are greatly enhanced.

Turning to exposure, the one golden rule must be to expose long enough. Let the mind be completely freed from all ideas of quick exposures and forced development, for such a course is absolutely and utterly impossible. The natural characteristics of the class of subjects are alone sufficient to contra-indicate short exposures even under the most favourable circumstances, for whatever may be the colour of the blossom, the green of the leaves, no matter what its tint, must have its due share of light. If the blossom be white or any delicate light colour, photographically speaking, instead of the exposure being shortened the very reverse is the case, for the very contrast between the flowers and foliage necessitates a "full" exposure in order to counteract any tendency to harshness. Yellow and red flowers, especially if dark in tint, suffer proportionately less by curtailment of the time of exposure; but though the result, pictorially, may be better than in the case of the lighter tints, the correctness of the colour rendering must inevitably suffer. Besides this, the conditions of lighting under which we recommend the work to be done are such as require a liberal allowance of time in exposure in order to produce artistic effects without harshness or heaviness.

But the question will be asked, "What constitutes a full exposure?" to which we can only reply that everything depends upon circumstances. The plate, the subject, the light, the studio, in fact, every single item in the process demands its share of recognition as affecting the all-important exposure. But a very few experiments in a new studio will give a good idea of what is requisite under normal circumstances, and any variations in plates, or light, or subject, can then be easily calculated and allowed for. As a rough idea, we may mention

that at a distance of three or four feet from a window about four feet by three feet in dimensions, and facing south, but without the sun on it, we are in the habit of giving from three to fifteen minutes, according to the subject, the lens being stopped down to about $\frac{1}{16}$. These lengthy exposures are made to suit a special development, as will be explained later, for under the same conditions of lighting and employing a normal developer, ten seconds with most subjects will suffice to produce what would be a good negative if it were a reproduction of any other object. But in order to obtain the detail in the abnormally deep shadows that is requisite to an artistic rendering of the subject, it is absolutely necessary to expose solely for those shadows, leaving the better lighted portions to be dealt with by a modified development.

Even these exposures are not abnormally long for the class of work, for we know that one master in the art of flower photography, to whom we referred in our previous article, used to be in the habit of giving as long as half or three-quarters of an hour, and that under a glass roof, though it is true the lens employed was a slow one, stopped down to its utmost limit.

These lengthy exposures are at times slightly inconvenient, from causes which lie with the flowers themselves rather than in the operation of photographing them. For example, the delicate sprays and pendulous blossoms of some flowers are so nicely balanced that the slightest movement suffices to set them in motion and so destroy definition. It may be supposed that a slight movement in the course of a lengthy exposure would scarcely affect the general definition, on the ground that the leaves and blossoms would resume their original positions when the motion was past. This they no doubt do to a certain extent, just as foliage in a landscape does in the quiet intervals of a gusty day; but it must be remembered that cut flowers offer the disadvantage, that by a slight shake they may be altered in their relative positions with regard to one another—the group may, in fact, be slightly rearranged. And again, in the course of half an hour, especially in hot weather, a cut spray is liable to droop, at least in a slight degree, not sufficient, perhaps, to present any palpable difference to the eye, though it may seriously affect the sharpness of the photograph. A far less common difficulty has been experienced with flowers which possess the curious property of opening or closing their petals under certain conditions of light; and it can be readily imagined that a blossom which, fully open when the exposure commences, gradually closes during the impression of the image, or *vice versa*, stands but a poor chance of being satisfactorily rendered. Still these troubles, in a measure unpreventable, may be reduced to a minimum if proper precautions are taken.

The development is perhaps the most important part of the proceedings, though by no means difficult if the principles on which it is "fitted," so to say, to the exposure, be mastered. We have spoken of giving exposures extending to fifteen minutes where a few seconds would suffice to make a photograph with ordinary development; to apply the same treatment to a film which had received the longer exposure could have but one inevitable result, a thin, veiled image, entirely useless for printing purposes, if indeed it were not entirely lost in fog—a result, in fact, commonly described by the term "burnt up." To remedy this a liberal dose of restraining bromide is the first and most natural resource, but this introduces another difficulty; while it restrains the energy of the development and controls the formation of the half tones, this action is exerted most powerfully upon the more feebly im-

pressed portions of the film, and the final result is little, if any, better than before. For, up to a certain point, while the half tones and finest details are struggling against the cheek, the high lights—the delicate blossoms—are acquiring density, and by the time the shadow details are produced, will have entirely lost all traces of gradation.

We have, then, to adopt means by which the “piling on” of density in the high lights is arrested during the time requisite for the gradual production of detail, and this is done by so constituting the developer as first applied that it is incapable of giving a dense image. To secure this end we greatly reduce the quantity of pyro employed; instead of the usual strength of three grains to the ounce, let it be reduced to one grain, or even half a grain. The effect of this will be that though the rapidity of the *appearance* of the high lights is in no way checked, they advance to a certain strength, at which they stop, however long the application may be continued, while at the same time the half tones and details are making steady if slow progress, and the outcome is a thin, flat, apparently useless image. But though so evidently lacking in contrast, the film retains in its better exposed portions a reserve of energy, or a capability for density, that upon washing and re-treating with a solution calculated to give density it at once acquires vigour, the high lights coming up to printing strength in a very short time, if not immediately; indeed, so rapid is this intensifying action that this portion of the process must be considered the most delicate and “ticklish” of the whole. Either alkaline, pyro, or silver intensification may be adopted, but we prefer the latter on account of its slower and more regular action, though it is true greater precautions are required in removing the hypo, for this must be performed after fixing. If alkaline pyro be used a strong addition of gallic acid may be used with advantage.

The exact details of the manipulation must of course depend upon actual circumstances, for no strict rule can be laid down; but if these lines be followed, success will not be difficult of attainment, and the quality of result will be superior to any that can be obtained by quicker development. The use of orthochromatic plates will form the subject of a separate article.

DEMONSTRATION by aid of the lantern is now a regular feature in the Public Schools of the district of Prescott, Ontario, having been recently introduced by the Rev. Mr. Blair, the Inspector of Public Schools there. This offer on the part of the Inspector is being gladly received and co-operated with by the teachers, trustees, and parents throughout these parts.

SOME little time ago a method of making oxygen without a retort was published, and after going the rounds of the scientific papers was little heard of again. As, however, we have recently seen the plan resuscitated, it may be as well to observe that it is entirely inapplicable where economy is at all to be considered, as the following calculations will readily show. Two pints of oxygenated water, an ounce of permanganate of potassium, and a pound of sulphuric acid, are mixed in the specified manner, and the product is five gallons of oxygen. These ingredients well bought could not be had for much less than three shillings, so that we may put down the gas as costing about sevenpence a gallon. We are so accustomed to estimating oxygen by feet rather than gallons that the unthinking might not note the difference; but when it is remembered that six and a quarter gallons go to make a cubic foot, and that thus an ordinary size gas bag would cost a guinea to fill, we think that few of our readers would exhibit their photographs by the aid of the optical lantern if such an expenditure as this were necessary.

In a recent number of the *Comptes Rendus*, M. E. Duclaux narrates some interesting experiments upon the relative powers of heat and of solar radiations to bring about certain chemical changes. A large number of organic compounds containing carbon, hydrogen, and oxygen were subjected to the action of heat and of solar radiation in the presence of air, nitrate of silver, chloride of gold, chloride of platinum, permanganate of potash, and other oxidising agents, with the result that all reactions of the nature of combination that can be brought about by the action of heat can be likewise brought about by solar radiation. The converse, however, does not hold good, for it was found that several decompositions that the sun's rays were instrumental in producing could not be established by heat alone. It was found that when permanganate of potash was used it acted in many cases in the dark, the ultimate products being identical with those obtained by sunlight.

THE use of the electric light in photographic portraiture being no longer confined to a single studio, it may be well to bring before our readers some account of a paper read by M. d'Arsonval at a recent meeting of the Paris Academy of Sciences, upon the subject of fatal accidents through the accidental interposition of the body in an electric current. Our readers may remember that the gentleman who had charge of the electric light in the first studio in this country where this mode of illumination was employed adopted the invariable plan of keeping one hand in his pocket when adjusting the carbons, so as to avoid all possibility of receiving a shock by the incautious handling of both points at once. There are, of course, other times and occasions where danger lurks, and, though fortunately there are no records of death through electricity in photographic operations, it will be well to be prepared for any *contretemps* that may thus occur. Passing by the theoretical part of M. d'Arsonval's paper, we arrive at his summing up, wherein he states that, in accidents under the conditions usually realised, the current kills by reflex action; “and,” he says, “I have succeeded in the majority of cases in restoring to life animals that have received shocks by subjecting them to artificial respiration. The practical conclusion to be drawn from this note is that it is necessary in electrical works to be able to practice at a moment's notice artificial respiration upon any one who has received a shock.” In relation to these remarks, M. Brown-Séguard describes a method that has been successfully employed by the Collège de France in bringing back arrested respiration, which he states to be far superior to that employed by Faure and others. “It consists simply in the application of a faradic current to the sides of the larynx on the skin, which is moistened or superficially excited. . . . We have found in comparative experiments, which remove all doubt, that, of all parts of the body, that which, being galvanised, has the greatest power in restoring respiration is the one we have mentioned.”

IN photography and the arts generally, the much-valued albumen of eggs has, for the sake of economy, often to give way, wholly or in part, to albumen from other sources, and there is a widespread idea that some of the nauseous-smelling albumenised paper from a foreign source met with in commerce is innocent of the most remote connection with feathers. But it has been reserved for the electricians to utilise still another form of (so-called) animal albumen. We read that a French Company employs on a large scale a method of electroplating organic bodies, such as flowers and insects, by the aid of an albuminous liquid obtained from snails or slugs, the mode of preparing which we detail for the benefit of those of our readers who may wish to try its capabilities in photographic operations. “Snail paper” would be a novel variation upon the well-worn title, “albumenised paper.” “A quantity of snails or slugs is first washed in ordinary water to free them from calcareous or earthy matter. They are then placed in a vessel containing distilled water, and are here left a sufficient time to give off slowly their albuminous matter. The albumen thus obtained is now filtered, and boiled for about an hour.” It is to be observed that as no coagulation is anticipated at this stage of this process, the substance must be very dissimilar to that ordinarily known under the name of albumen. Perhaps gelatine would be a more suitable term to employ: we then might have “snail plates.”

WE have kept our readers *au courant* with all matters relating to the Paris Congress on star charting by the aid of photography, and we have now to chronicle the close of the Congress. All working details are arranged, and various committees appointed for different phases of the routine, and the working out of the plans decided upon. One sub-committee was appointed to occupy itself with "the applications of photography to astronomy other than the construction of the map, showing the importance of all these applications and the relations which it is important to establish between these different kinds of work." Mr. Common and M. Janssen were appointed to carry out this portion of the plan.

EXPERIMENTAL work of various kinds in connection with the decisions of the Congress was divided into ten classes, those only of which that will interest our readers being Nos. 5 and 9 on the list. The former, entrusted to the observatories of Algiers, Mendon, and Potsdam, consists in a "Study of the deformations of films." The last but one (9), and perhaps most important in the list, is, "The study of formulae for the preparation of plates in accordance with the general rules laid down by the Conference." One of our countrymen is again put to this important labour, the name of Captain Abney being linked with that of Professor Eder.

PAPER NEGATIVES IN ORDINARY SLIDES.

THAT we have reached finality in regard to the mechanical arrangements for the exposure of paper or film negatives, no one will, I think, yet claim, though certainly it must be confessed that a vast amount of care, attention, and undoubted mechanical skill have been lavished upon the task. The roll holders or roller slides leave apparently little to be desired or expected so far as their fitness for the purpose intended is concerned, and film carriers are so numerous and ingenious in their construction that it seems well nigh impossible to suggest a new form.

Yet, despite the mechanical perfection of the modern roll holder, it cannot be denied that a certain amount of prejudice exists against it; it is almost as if it were too perfect a piece of mechanism, or only short of absolute perfection in its failure to work automatically instead of requiring, as it does, a considerable amount of methodical care in its use. I have had two or three days "out" in company with possessors of roller slides of various makes, and these happy beings, though mightily proud of their mechanical toys, seemed to pass the time in a constant fever of anxiety as to whether they had strictly performed that which they ought to have performed, and left undone that which they are told not to do. First, it is a question whether the machine has been wound up to three "clicks" or four, then there is a doubt as to whether it has been set since the last exposure or not, and it is scarcely to be wondered at that, in the bother of deciding these important matters, count is lost of the number of actual exposures made. The last trouble may of course happen with double slides, or, better still, with a changing box, but there is then less excuse for it, as the operator then has no distracting mechanism to draw his attention from his legitimate business.

Then, as regards the film carriers, all those that I have seen are either unnecessarily bulky or heavy, or unwarrantably expensive for the work they are expected to do, and leave much to be desired in the direction of an entirely new form of slide for film work. But even this I know would not satisfy everybody, however perfect it might be, for there is a strong tendency to cling to old associations and existing apparatus. Many men—myself, I confess, amongst the number—are unwilling to go to the expense of new slides while the old ones can be utilised, or to have existing apparatus altered to suit a new "fad," which may prove to be but a passing one, and such, failing a really efficient "carrier" at a moderate price, are likely to adhere to the use of glass, or else cast about, as I did myself, for a home-made substitute.

The problem is to utilise the ordinary double slides without in any way interfering with their employment for glass, if necessary. The film carriers already in the market are devised on this principle, but, as I have remarked, they are either too clumsy or too expensive. The neat and efficient Eastman carriers are very good for American slides, but they are too thick for the lighter class of English portable backs, and

probably to make them any thinner would be to destroy their efficiency. The same thickness of wood as at present employed would answer equally well for a *double carrier*, i.e., for carrying two films instead of one, if it were provided with a double metal flange, but it would then necessitate a slide made specially to suit its thickness, or the slabs of wood would have to be planed down to the dimensions of each individual slide, a rather inconvenient arrangement for English photographers.

The first idea that suggests itself is naturally the old one of exposing through a sheet of glass laid in the slide, and against which the paper or film is pressed; but this has several disadvantages, chief of which is the necessity for allowing for the thickness of the glass in focussing. My own experience with this method, working as I did paper and glass at the same time, is that when one of the paper slides went in to the camera, I managed to recollect it was paper after the exposure was made without alteration of focus; but as I was working 12 × 10 with an eighteen inch focus lens, the result was not entirely ruinous. However, the first day's experiment led me to vary the process by placing the paper in front of the glass, laying it carefully down in the rebate of the slide, and placing the glass upon it to press it and keep it in position. So far it was moderately though not perfectly easy, for a 12 × 10 sheet of gelatinised paper is not quite as tractable as a rigid piece of glass, wood, or metal, under the circumstances; but when it came to *closing* the slide, I felt inclined to exclaim, "*Ille labor, hoc opus est!*" for then indeed the trouble commenced. Whether the paper created any greater tendency on the part of the glasses to leave the rebates I cannot say, but it is certain they *did* every time I tried to close the slide, and of two sheets that I did eventually succeed in "fixing" one got torn by the sliding shutter, a corner having managed to escape from the rebate on the under side. For smaller sized negatives, however, this plan answers fairly well as a makeshift; I have used it for papers 7½ × 5 without trouble.

But in using the ordinary glass slide for paper or films a very great amount of space is wasted and useless material carried if only two negatives are placed in each, and it occurred to me long since that for travelling purposes the slides might be used for storage as well as for exposing purposes if a suitable carrier, much thinner than those usually employed, could be devised. During the winter months I have endeavoured to develop the idea and think I have succeeded fairly well, though it is true the system has not yet been put to the test of actual practice on a journey.

The plan as originally conceived was to construct a number of inner frames, or carriers of cardboard, each to hold two films or papers separated by some non-actinic medium, and to be of such thickness that two, three, or more would just fill the space in the slide usually occupied by the two glass plates and intervening metallic shutter. In this manner each slide would carry, in addition to two surfaces ready for exposure in the ordinary manner, a reserve of films which only require their positions in the slide changing in the bedroom of the hotel at night, to bring two fresh exposures into position.

I constructed a number of double mats of cardboard, glued together along three edges, the fourth being left open to receive the two sheets of gelatino-bromide paper with an intervening leaf of opaque paper. But the process of making was troublesome, the carriers were fragile and easily damaged, very difficult to keep flat, necessitated the use of paper smaller than the glass plates for which the slide was constructed, and, finally, required an alteration of the focus to compensate for the thickness of the cardboard. It then struck me to cause the papers to adhere to a single sheet of cardboard, but the difficulty was to find a suitable adhesive. I tried first of all diachylon, as suggested I think by Professor Stebbing, but I am sorry I cannot congratulate him on having led me to victory; the paper adhered but slightly when it ought to have done, and peeled away in a very reluctant manner when required, and the traces of the adhesive left on the back caught and harboured dirt to an extent that would have utterly ruined any negative. Next I tried gumming or gluing the edges of the sensitive paper to the card, but this necessitated the *cutting* of the exposed sheet, leaving a narrow strip adherent to the card support, and so increasing the thickness of the latter with each exposure, as I found it quite spoiled it to remove the strip by damping. However, the idea seemed an improvement, so I next cast about for a support

that would stand the damping-off of the edges of the exposed sheets. This I found in very thin sheet ebonite, which I obtained without much difficulty, about the thickness of a visiting card, or perhaps a little thicker, flexible, and translucent, or even transparent to a strong light. This last raised a doubt in my mind as to the safety of the ebonite as a division between the two exposures, so I had to make a further search and at last hit upon ordinary ferrotype plates, which are even thinner than the ebonite, cheaper, and, what is of more importance, quite opaque.

I do not know whether all ferrotype plates are the same thickness, but they can be obtained up to fourteen inches by ten inches in size at about six or seven shillings a dozen. Mine I ordered cut to the size I wanted, and I find that under pressure about a hundred of them go to the inch. With two thin negative papers attached I can comfortably get a dozen—that is two dozen exposures—into the ordinary double slide; so that with the usual equipment of three double slides, six dozen plates, or rather films, can be taken on a tour in the same space as many single glass plates. There is no liability to damage from contact with impure packing paper nor from scratching, as the sensitive films are pressed gently but firmly in contact with one another, and if ordinary care be taken in handling them when the slide is opened they are as safe as if in grooved boxes. There is sufficient “bend” or “spring” in the plates to make the block somewhat elastic, so that it “gives” to the pressure of the rebate of the slide, and so the two outer exposures are kept accurately pressed into correct focal position. When two exposures have been made it is only necessary to remove one carrier to the opposite end of the block, and this will bring two fresh surfaces into use; if this be done methodically, say, from the odd to the even numbered side of the slide or *vice versa*, no difficulty can occur about wrong exposures. C. BECKETT LLOYD.

(To be continued.)

ACCESSORIES OF THE LANTERN.

CHAPTER VIII.—THE MIXED GAS JET.

THERE still exists among makers of mixed gas jets much misapprehension of the principles that have to be adhered to, in order to obtain the best results. Many jets in the market which are made on the mixed gas principle—in that both the gases, oxygen and coal gas, have to be put under heavy pressure in separate gas bags—are so defective that they yield a light of less power than an ordinary blow-through jet. Some that have been tested could not be made to give a better light than 150 candles, and few of the better class jets are more powerful than 300 candles, even with a high gas pressure.

A good open, or blow-through, jet gives a light of 200 candles; and a properly made mixed gas jet, burning coal gas as the hydro-carbon, should be capable of giving any power of light between 200 and 600 candles, according to the gas pressure.

If pure hydrogen was used instead of coal gas, the available aperture of the jet nozzle would be lessened, and the best light that could be had would probably not then exceed 300 candles. It is found that the aperture from which the gases issue cannot be enlarged beyond a certain size, as either a roaring noise is produced or the flame of the burning gases passes back into the mixing chamber and the light “goes out.” Hence coal gas is far superior to pure hydrogen for limelight purposes, as it admits of a larger aperture being employed, and this causes a corresponding increase in the illuminating power of the jet.

It is interesting to compare modern jets with the apparatus used in 1820, when the limelight was first applied by Lieutenant Drummond, the inventor, to lighthouses. A book on science, published over fifty years ago, gives a woodcut and description of the original apparatus, or “lamp,” as it was called, the appearance of which was as unlike the jets now made as it well could be. The lime was not a cylinder, but was of the shape of a small marble, three-eighths of an inch in diameter. This ball was perforated and strung on a vertical platinum wire. There were two long nozzles, like jewellers’ blowpipes, proceeding from a mixing reservoir for the gases; the points of these nozzles were turned toward each other, and the lime ball was placed between the two points. There were thus two flames acting on opposite sides of the little ball, which would consequently throw

off light in all directions. The power of this double limelight is stated as being only equal to 122 wax candles, and yet the gas pressure was that of “about one atmosphere!” The little ball was made to revolve by clockwork, which also allowed it to slip down the platinum wire after being in use forty minutes, another ball falling into position between the two blowpipes at the same time. Pure hydrogen was used, the quantity of the gases burnt per hour being four cubic feet of hydrogen and two of oxygen. All lanternists will feel grateful for Lieutenant Drummond’s invention; but for his ingenuity we might now be compelled to choose between an oil lamp and the arc light for the optical lantern.

Those who used the limelight in its primitive form adopted very small apertures in the blowpipes, through which the gas was forced at an extreme pressure. The mixed gas jet was, in consequence, styled the “high pressure” jet, a title which is not so applicable now, as we can get an excellent light with a low pressure, such as that produced by a half-hundredweight, on a gas bag of eight cubic feet capacity. Owing to the force with which the gas issued from the jet, and also in part to the faulty construction of the nozzles, it was found that brass nipples sometimes become corroded and rotten by the action of the great heat if the limelight was kept in use for a long period. In order to avoid this wearing away of the nozzles, the custom was introduced of tipping them with platinum; and although it is a fact that jets made on modern principles—having large apertures, and working with a low gas pressure—are not a whit better for having the more expensive platinum tipped nipples, but are really worse off than if they had brass ones, yet the makers still adhere to the old custom, and the catalogues of opticians always mention, as a special virtue, that their best jets are tipped with platinum.

The reason why platinum tips are not advisable with the large apertures, is that it creates a discontinuity of the metal near the extremity of the nipples, which in a short time detracts from the smoothness of the internal surface. The result is that a small eddy in the issuing gas is caused, accompanied by a roaring noise, and the nipple is gradually destroyed by the corrosion of the brass at the point where it joins the platinum.

If platinum must be employed, the entire nipple should be made of that metal; such a nipple, one inch long and a quarter of an inch diameter at the larger end, would be very expensive compared with brass, but it would be practically everlasting. Platinum being a very poor conductor of heat, a nipple of this metal is not heated to the same extent as a brass one, hence a somewhat larger aperture can be employed; this advantage, however, is only to be obtained by having the platinum about one inch long. Brass nipples answer every purpose, as they will remain serviceable for a hundred exhibitions at least.

The internal construction of the nipples is a point of great importance. The bore is made by drilling the nipple through one-third of its length so as to leave a hole one-eighth of an inch diameter; the remaining portion is then perforated with a smaller drill. There is thus left a shoulder in the bore, which interferes with the flow of the gas and tends to create a roaring noise when the jet is in action. This shoulder should be removed by inserting a specially made rimer, and the bore rendered as near like a cone as possible, and with a perfectly smooth surface. The same system of cutting away projections should be followed at the place where the nipple is screwed to the nozzle leading from the mixing chamber.

The real secret of getting a powerful noiseless light with mixed gas jets is simply to have the current of gas, issuing from the nipple, perfectly smooth and free from eddies. A simple way of testing a jet is to blow air through it with moderate force; if there is a hissing noise at the nipple, the jet will hiss when used for the limelight; if it is noiseless when tested with the breath, it will probably be noiseless in the lantern. The size of the orifice of the nipple should be one-sixteenth of an inch in diameter for discs of fifteen feet; when discs of about twenty feet are desired, the aperture may be increased to one-twelfth of an inch. If the bore is made larger than one-twelfth, it will be only workable with a high gas pressure; with a low pressure the flame would “pass back.”

The external shape of the nipple may be a cone, the apex of which should not exceed one-eighth of an inch in diameter. There is a happy medium to be adopted in the thickness of the metal surrounding the bore—it should not be as thin as paper, as then it would not last long;

on the other hand, if there is too much metal round the orifice, the light issuing from the lime will be obstructed to some extent, and by the undue heating of the nipple the flame may travel back to the mixing chamber. A brass nipple of large aperture will work well in this respect if its diameter, at a point half an inch from the apex, is made three-sixteenths of an inch, and the shape is a cone tapering to one-eighth of an inch at the orifice.

The nipple should be put at an angle of 45° with the lime pin. This angle will be found to give the brightest light. The lime pin need not be upright; it is preferable for it to make an angle of 20° with the vertical, so that the light will be thrown downwards to a slight extent, and there will be then no possibility of the nipple causing a shadow on the screen during a lantern exhibition. ALBERT WM. SCOTT.

ON STEREOSCOPIC WORK.

[A Communication to the Manchester Photographic Society.]

IN bringing before the Manchester Photographic Society on this occasion the subject of stereoscopic work, it may be that I shall lay myself open to a suspicion of plagiarism, since within the last few months papers on the same subject have been given at various other Societies in different parts of the country, and these have been also further supplemented by direct communications to the photographic journals.

Having, however, had it in my mind since the commencement of the present session to prepare such a paper in readiness for a favourable opportunity of communicating its contents here, I have purposely abstained from reading up current matters on the subject, so that I should thereby be more likely to pursue an independent line of thought.

It has been matter for surprise to many people who are conversant with the history of the stereoscope, that an instrument of such scientific value, which, when used in conjunction with suitable photographs, is capable of imparting both instruction and real pleasure, should have enjoyed a lease of only some twelve or fifteen years popularity, and then began to decline so rapidly in public interest that in less than thirty years from its introduction to the scientific world in a practical shape it should have fallen almost completely into disuse. Whether it was that the exceptional favour with which the instrument was received when its capabilities became known gave rise, as is usually the case in such circumstances of sudden popularity, to inferior productions of the "cheap and nasty" type, or whether it was that the vile rubbish in the shape of stereoscopic slides, rapidly drifting into the region of the indecent, with which the market soon became flooded, and which largely contributed to the passing of Lord Campbell's Act for the suppression of vice, is not for me to say, but the fact remains that just as quickly as the stereoscope had risen into popularity only a few short years previously, so quickly did it begin to decline in favour, and in a very little while, as if suffering from the effects of evil companionship, it seemed to be tacitly regarded as an instrument of barely average respectability.

As regards the optical principles on which the construction of the stereoscope is based it is not so much my present intention to deal, that part of the subject having been ably treated by several of the contributors of papers already alluded to, as well as by a series of chapters in *THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC* for the present year by Mr. J. Traill Taylor, whose thorough grasp of the most abstruse problems in optical science is all but universally admitted. My object is rather to point out the utility of the stereoscope as a means of giving a more accurate idea of the natural form, proportion, and relative distances of the parts in a photographic picture taken specially for binocular inspection than can possibly be formed by looking at the same picture when taken microscopically, or by means of one lens only, and in that view of the matter to point out the educational value of the stereogram to artists who have not many opportunities of making their drawings direct from nature.

Moreover, I think it will be admitted that an attempt to revive a taste for stereoscopic work is not inopportune in this Society at the present moment, seeing that I am now addressing what may be said to be practically an entirely new generation of photographers, amongst whom the stereoscope and its powers are, to a considerable extent, very little known, although the means of producing suitable work for the purpose are now, by reason of the present exalted rapidity of gelatino-bromide plates, vastly superior to what they were a dozen or so years ago.

It is true there have not been wanting of late years occasional

though it must be admitted tardy, indications of a revival in stereoscopic work, which have led some sanguine people to express the opinion that before many more years elapse this almost forgotten branch of photographic art will be again to the fore, and in greater force and beauty than ever. Personally I see no reason why this desideratum should not come about quickly; on the contrary, there is every reason that it should.

I hardly need point out that the principle of the stereoscope consists in the union of two pictures dissimilar from each other in so far as that they are photographed from two slightly different standpoints, the difference between those standpoints being about equal to the average distance between the two human eyes, and thus a third picture is formed in the stereoscope by the superposition of one image on the other; the resulting combination being conveyed to the brain gives the same idea of solidity and relief as that derived from the actual sight of natural objects. The principle is readily illustrated by the simple expedient of photographing, by means of a binocular camera, a ball, on one side of which a black cross has been made. In the example shown you will perceive that the cross is perfectly rendered in the view taken by the left-hand lens, whilst the right-hand lens, being a different point of sight, does not depict so much of the cross on that side as to give a completely detached image of it.

The principle of binocular vision was known to Euclid, and dilated upon by him in his treatise on optics more than two thousand years ago. The subject was also further treated upon some centuries later by the celebrated Greek physician, Galen, and still more recently by Baptista Porta, Leonardo-da-Vinci, Agnoloni, and others; but the idea of uniting the two dissimilar pictures as seen by the right and left eyes by means of an instrument, afterwards to be called the stereoscope, first occurred to Mr. Wheatstone in or about the year 1838, when he contributed a paper on the physiology of vision to the British Association, then being held at Newcastle, and exhibited an instrument which subsequently became known as Wheatstone's reflecting stereoscope.

I have here a sketch, or diagram, of this instrument; but the stereoscope did not become popular until it appeared in a greatly improved and more portable form from the hands of Sir David Brewster, about the year 1852, at which period Archer's collodion process had just been made public property, and it was a process supremely adapted to the production of stereoscopic work. About this period, also, Mr. Dancer, an optician, then of great repute in this city as a scientific pioneer, introduced the binocular form of camera, by means of which, with its twin lenses, the operator was able to take the two pictures with one exposure, thus obtaining an uniformity of light and an identity of conditions which could not be satisfactorily secured where two separate exposures had to be made, as in the case of the Latimer Clarke principle, where the camera was mounted on an arrangement of parallel levers of the nature of the pantograph and the two exposures made separately.

The use of stereoscopic photographs for book illustration suggested itself, more than thirty years ago, to Professor Smyth, when he tried the experiment in his work on *Astronomical Observations at the Peak of Teneriffe*, in order, as he tells us in his preface, to keep a salutary check on the pencil, or long bow, of the traveller. Photography was, however, at that time too much in its infancy to bring out the true value of such a method of book illustration, although the work was extremely well received at the time, and fully bore out the wisdom of the experiment. If, however, with the improved means we now possess of dealing successfully with life and rapid motion, I venture to think that such a plan of illustration, especially in the case of standard works on science, would be both wise and profitable.

It has been objected as against stereoscopic pictures that they fail to give a true idea of the incidents of life and motion as seen in nature, and that there is a certain rigidity about them which, as I understand the spirit of the objection, is somewhat analogous to a human being in a state of catalepsy—where you have the form and semblance of life, but at the same time you have the stillness and fixity of death. I admit that there was considerable force in the objection at the time it was made, when long exposures were a necessity, but the criticism does not now hold good with the means we have within our reach of securing instantaneously the fleeting and ever varying effect of nature.

Again, the superiority of a stereoscopic over a monoscopic picture is attested by the fact that the latter can easily be made to misrepresent a subject, whilst in the former case such treatment is practically impossible.

I remember once being concerned as a witness in an arbitration case, where the plaintiff's counsel, after stating his case, pointed triumphantly to some photographs which had been taken to establish the justice of his case, with the remark that the sun could not lie;

whereupon the opposing counsel, who seemed to know a thing or two, or thought he did, on these matters, proceeded to explain in technical language that by doing so and so, and omitting to do something else, the sun could be made to lie, and lie most vilely.

Further, we all remember that not very long since Mr. Heywood showed on the screen, at one of the lantern meetings, how an innocent negative was caused to tell a deliberate lie, by representing a small jutting rock of only a few cubic feet dimensions as a frowning precipice of mountainous magnitude.

I am not greatly surprised at the fact that most artists of eminence rather eschew the method of copying their works direct from photographs (of course, I am now speaking of pictures taken by one lens only, and not stereoscopic pictures), especially in the case of landscape painting, although both Mr. Walker, of the Owens College, and Mr. Madox Brown have expressed to me their high appreciation of the help which photography gives to the artist in matters of detail, such as the form and anatomy of all varieties of trees, rippling water, sedgy foregrounds, and the like; but as regards the picture, as a whole, no artist who has a proper conception of his work will trust to a monoscopic photograph as his sole guide when he has the opportunity of seeing with his two eyes the real scene as depicted by nature herself.

I do not set myself up as an artist, either in practice or judgment, but amongst the very few accomplishments acquired in early life I learned to draw a little, and the pursuit is still a very enjoyable pastime when I have leisure to practice it.

I have here a copy of a drawing made by me a few months ago; it was scaled out as carefully as possible by the help of a simple view meter of a kind often used by artists, namely, a rectangular opening, of the same proportions as the boundary lines of the picture, cut in a piece of cardboard, and held at such a distance from the eyes that no more than the desired angle would be included, otherwise the work was entirely freehand, and for the time being the camera was abandoned. When the picture was completed, but not before, I took a photograph of the scene from the exact spot I had painted it from, using a lens to include the same angle of view.

I will say nothing of the two pictures thus produced, except that there is a marked difference between them; and, further, though at the risk of being thought egotistical, I think all will admit who know the spot that the drawing, though containing many imperfections, is more suggestive of the reality than is the photograph.

In the case of stereoscopic work, however, the photograph would not be similarly misleading, there would be no making the molehill into the mountain, nor *vice versa*. Everything falls into its right place, and a correct idea is given of the relative size and distance of every object that goes to make up the picture. There must, of course, be no tampering, even with the binocular camera, in the shape of tilting, swinging, or other unorthodox devices, in order to reach the top of a tall tree or spire, that is, if the truth of nature is to be faithfully recorded.

Since reading the above paper it was suggested to me that I ought to have said something about the mounting of stereoscopic pictures in order to make my communication more complete. I had, perhaps wrongly, thought the matter was of too simple a nature to refer to, but as I can supply the deficiency in a very few words, I will proceed to do so.

In the first place, I may point out the well known fact that all photographic lenses give the image on the plate in an inverted condition; consequently, in the case of a binocular negative, the image taken by the right-hand lens is seen on the left-hand side when the plate is turned round so as to see the picture in its proper non-inverted state; on this account, in mounting the prints, it is necessary to transpose the two halves by mounting the right-hand picture on the left-hand side of the mount, and the left-hand one on the right-hand side.

The transposition would, however, not be necessary if the stereoscopic picture were made, as it is sometimes done, by means of a quarter-plate lens and the camera moved laterally between the two exposures, because in that case there are two separate negatives, and each of them can be righted independently of the other. Then as regards the trimming of the prints, this must be done with great care, so that when the slide is finished the corresponding middle distance objects in each of the two pictures are, as nearly as possible, 2.75 inches apart, which amount may be taken as a safe average distance between two human eyes. Care must also be taken that the bottom edge of the picture cuts the objects off in one case exactly as in the other.

In trimming the prints, some people prefer leaving more subject on the outside margin, or the right and left side, so as to make the photographs look larger when mounted; but otherwise there is no advantage in doing so, as the overlapping portions are, of course, not stereoscopic.

For my own private collection of stereoscopic slides, I do not care to include paper ones at all, glass being so much superior as regards giving fineness of detail and general delicacy that no paper prints can approach them. The camera I use for making my glass transparencies, and which I have brought here for inspection, is simply an extended form of the ordinary binocular, having a partitioned front extension of two dark chambers so that no light can get to the lenses except that passing through the negative, which is placed in a carrier at the front, and the whole pointed to a northern sky. The transposition is made automatic by putting the negative in the carrier with the film side outwards.

I have already extended my remarks to far too great a length, seeing that there is other business before the meeting. I have done so, however, purely from a desire to give an impetus, it may be a feeble one, to the revival of this once popular, though now neglected, branch of photographic art.

J. S. POLLITT.

HALATIONS IN NEGATIVES.

CHAPTER I.

ALTHOUGH the subject of halation in negatives has frequently been brought under the notice of photographers, yet it has not received that amount of attention which its importance demands.

Photographic halation may be briefly defined as an encroachment of the high lights on adjacent shadows. The defect in its most aggravated form may be said to date from the time of the introduction of photography on glass, but no attempt at giving a rational explanation of the phenomenon seems to have been made until some years after Archer had introduced the iodised collodion process, when photographers, who had to delineate objects containing very abrupt contrasts of light and shade entailing a long exposure, were dismayed to find that the high lights had encroached on the deep shadows and interfered with the sharp definition of minute details. Especially was the evil noticeable in photographing interiors—cathedrals for instance, where a window formed a portion of the picture to be taken. In such cases the sash bars and mouldings, instead of being sharply defined, were all but obliterated in one blaze of illumination. Various conjectures were, from time to time, thrown out as to the cause of this peculiar phenomenon, but it remained for Mr. Marlow to discover the true cause, and he, in the year 1861, contributed a paper on the subject to the Photographic Society of London. In this interesting communication Marlow ascribed the phenomenon to the passage of the strong beams of light, first through the film of iodised collodion and then through the glass, from the posterior surface of which they were reflected back into the film at points different from those by which they penetrated it. As a necessary consequence portions of the sensitive medium were actinically affected by radiations which did not come direct from the lens. A diagram accompanying Mr. Marlow's communication rendered his explanation easily comprehended. Although the demonstration was complete, still photographers seemed to treat the matter with great apathy and took no steps to apply an efficient remedy.

Some years afterwards when Major Russell, ignorant of what Marlow had done, introduced his dry process with bromised collodion and alkaline development, he not only proved Marlow's theory to be the correct one but devised a very efficient remedy, or rather preventive, which consisted in destroying the reflecting power of the glass surface by backing the plate with a coating of a non-actinic pigment, such as sepia, &c. The pigment was easily washed off after exposure and previous to development.

It may here be mentioned that bromised films are much more liable to these back reflections of injurious light than are films which consist mainly of silver iodide, inasmuch as light in passing through this latter medium must necessarily be reflected back of a less actinic character than when it has to pass through the whiter and, therefore, more actinic bromide.

But besides preventing optical halation or, as Russell termed it, *blurring*, the backing of the glass plate with non-actinic pigment in optical contact with the surface confers other advantages, inasmuch as transmitted light is thereby absorbed while the sensitiveness to weak radiations which do not pass through the film remains the same. Moreover, solarisation of the high lights does not set in so soon as would otherwise be the case, and details in them, such as clouds in the sky, will bear much longer exposure without being obliterated. Nevertheless, we must not expect that the most perfect kind of backing will altogether prevent optical halation in cases of strongly contrasted lights and shades and protracted exposures, inasmuch as every known body, however non-actinic its colour and non-reflecting its surface may be, will eventually when strongly illuminated, reflect

sufficient light to give a picture in the camera. Yet there can be no question but that by means of a light absorbing backing, the capability of faithfully rendering violent contrasts of light and shade is greatly extended, so that we are thus able to give a much longer exposure for details in the deep shadows before the actinic rays from the high lights can effect any injury by reflection.

It has been proposed to stain the film with some non-actinic dye so as to prevent injurious light from passing through and being reflected from the back surface. Such a plan would certainly prevent optical halation, but then it has the great drawback of preventing light from penetrating the film and therefore cannot be recommended. When we bear in mind the fact that the image, in an alkaline developed film, is entirely derived from the silver bromide within it, it will readily be seen that the high lights must necessarily be destitute of vigour because light has not been able to penetrate the film sufficiently deep to render the bromide therein amenable to development.

Having thus briefly glanced at the cause of, and remedy for, optical halation, I propose in another chapter to append a few observations on another class of defects to which bromised films are necessarily liable.

GEORGE DAWSON, M.A., PH.D.

THE RIVAL PHOTOGRAPHERS.*

HAVING stayed so long in Mr. A.'s studio, and treasured up all his remarks and sentiments as regards the photographic art, I think we can safely leave him and visit his rival on the opposite side of the street. If you are at all inquisitive, I feel sure you would like to know also what has become of the poor wretch who had such a warm time of it while trying for a "crib" in Mr. A.'s service. Well, I will tell you all about him.

This poor fellow had had a very bad time of it; business had been very uncertain with him, and he was fairly down in his luck. Any one with a spark of sympathy can fancy his feelings when leaving the studio where he knew he could do good, but where he morally got "the kick out." When at the door he took a last look at the show-*eases* and, notwithstanding that it was such poor revenge, he experienced a feeling of satisfaction, for he well knew that such work would before long make Mr. A. smart for the disappointment *he* had had that morning.

Looking up he saw another photographer right opposite, and, while crossing, slowly wondered within himself what his luck would be there. Indeed, the question suggested itself if any one required a retoucher at all in these parts. He had a look at the show-*eases* and saw some very excellent specimens. Thoroughly good as photographs, and (oh, joy!) they were all *retouched*, and very well done into the bargain. He felt his only chance here could be that Mr. Z., through press of business, might require extra help. Hoping for the best he went upstairs and inquired for Mr. Z. He was occupied at the moment, but would be able to see him in a few moments.

While awaiting the arrival of Mr. Z. he had a look around the show room. The photographs, unlike those of Mr. A.'s, were all *retouched*. At a glance, too, he saw that he was in a house where really first-class work was being turned out. There was a general air of business about the place that gave him hope. Several sitters were waiting, and others were looking about, evidently wanting something and seeking for something to decide them in their choice. It struck our friend that this was the house doing the business, although he was told at starting that *all* the good work of the place was done by Mr. A. and Mr. Z. Truth to tell, they were the two leading photographers both for position and connection, as well as for excellence of productions. For he it well understood, Mr. A. was as good a photographer as could be found, and so, too, was Mr. Z., the only real difference being, the latter was more business-like and consulted the feelings and opinions of his patrons, whereas his rival tried to teach his customers that what *he* considered best really was so. I need not say which gained the advantage.

You will be, no doubt, astonished when I tell you that the object of all this difference of opinion was the retoucher's art. The one would not have it at any price, while the other considered that, in judicious hands, it was most powerful in producing successful, if we must not say *perfect*, photographic portraiture.

Before he completed the round of the show room a smart, business-like man came over to him, and he felt he was in the presence of the proprietor.

"Mr. Z., I presume?" ventured our friend.

"The same. What can I do for you?"

"I am a retoucher," suggested our friend, and he anxiously hoped for the best.

"And want work? Good!" He was a shrewd man, quick to understand, and kindly to deal with. "I will not ask you if you have any specimens—I don't believe in that system. Have you been to any other photographer in this town?"

"I have only arrived this morning, so could not make many calls. I have been, however, to Mr. A.'s studio over the way."

"Ah, yes! I don't suppose, though, that you got any work from there."

"He has not one *retouched* subject in his show rooms."

"No! He'd do more work, however, if he had. It is a great pity to see any one so positive in their opinions as to absolutely refuse a fortune. He is a splendid photographer, I do not know a better; but as for retouching, he won't hear of it. Of course you can see I have all my negatives retouched. I have a competent artist, and pay him a good price, and his work is most satisfactory. I do not patronise 'the cheap and nasty.' I want what is really good, and am contented to pay a fair price for it. Do you wish for *piecework*, or would you engage for the season?"

"I would prefer for the season."

"Well, the fact is I have an opening at this very moment. Indeed, had you not called, I would have inserted an advertisement in next week's BRITISH JOURNAL OF PHOTOGRAPHY. I have had an artist for the last three years, but his sight has become very weak. I recommended him to take a rest and have good advice, lest his eyes should become too feeble to continue at such trying work. I have given him three weeks' holiday, and if you like to take his place during his absence I have no doubt we can arrange. If we suit each other at the end of that time the season here will have begun, and there will be ample work for you for at least five months."

"I will be very pleased." Indeed, our friend was very glad to get fixed up, and more especially in a place where the proprietor took so active an interest in the working of his business as Mr. Z. seemed to. "May I ask what style of work you prefer?"

"I have no particular style to which I pin my faith. I consider *each* negative requires a special treatment, and a retoucher should use such means as he thinks best to enable it to yield a successful print. I do not wish my negatives to be over laboured. All my negatives have the utmost care bestowed upon their production, and I look upon retouching as a *necessary help* towards securing a pleasing and successful portrait."

"I am glad to hear you say so, as personally, although I have looked upon my line of work as absolutely essential to successful portraiture, I have always considered it a *help*, and as such should join the operator in producing a negative to yield the desired result."

"Certainly. I object strongly to the *preponderance* of retouching, or to its becoming obtrusively visible. Above all, I want judgment and discretion used in the treatment of my negatives. Of course I mean this generally. There are exceptional cases, I know, where customers require the most absurd alterations, but even these can be done with such judgment as not to ruin the general effect of the picture. I will show you a few negatives done as I prefer them, and you can tell me if your style will produce similar."

This was a sound, practical manner of treating the case. But, again, this was a photographer who thoroughly *knew* what he wanted. He knew to what degree retouching could help him in producing successful pictures, and to that extent he employed it. He did not, however, because he had his retoucher to fall back upon, relax his efforts to produce perfect negatives. On the contrary, he made every endeavour to make the retoucher's labours as light as possible by providing him with the best of negatives to work upon. In my own experience I have had many negatives that I scarcely knew what to do with them, they were so good. There was so little to do, and I knew if the photographer did not see a *lot of work* he would grumble at the price paid.

These cases were very embarrassing at times. I felt almost obliged to put a lot of work on to justify my price, as otherwise, judging by past experience, my customer would not be pleased. But where to put the required work was the trouble, as more than a small amount would tend to injure the negative instead of bettering it. The prevailing idea with the generality of photographers is that they pay for *labour*, not *judgment* and *artistic feeling*. To this fact may be traced many of the defects in the general run of the retouching of the present day.

Mr. Z., having left our friend for a few moments, returned with half a dozen negatives, just to show him what he thought upon the subject.

"Now, you see some of these negatives have very little work upon them, but there is enough to get the desired result in the print."

"Perfectly so. To work them any more would be to do them more harm than good."

"Now that is the class of work I want you to do for me. I want judgment, not dash away, to be the system upon which we work."

In a few words he stated his terms, which proved fair and satisfactory to both sides. Our friend accepted, and there and then started on his duties. At this moment a customer arrived, and Mr. Z. went to attend upon him.

"What can I do for you?"

"I want to be photographed. Are you the best photographer in this town?"

This was rather an odd question, and somewhat puzzled Mr. Z. It was not often he felt knocked out of time, but this question and the abruptness with which it was put very nearly did it.

"Well," said Mr. Z., "I would not like to flatter myself that I am the best photographer here, but I can guarantee that I will produce a successful portrait for you."

"You all say that, but your results fall very short of your promises. I may, perhaps, be a very difficult subject, but I have no objection to pay for extra trouble so long as I get a good picture. I have had some pictures done at Mr. A.'s studio opposite, and he promised me a really truthful likeness. I never saw such frights in my life. One would think I hadn't washed my face for months."

"Yet Mr. A. is a first-rate photographer."

"Well, if that's your opinion I'm off."

Mr. Z. saw at a glance where the trouble lay. The customer had freckles, &c., on his face, all of which could have been easily retouched away, but Mr. A. never sullied his pure art by a touch from a retoucher's pencil. Of course it was bad taste of this gentleman to dispute the correctness of the photograph. Still, bad taste or not, he would not have another batch similar, and was going when Mr. Z. stopped him.

REDMOND BARRETT.

ODDS-AND-ENDS.

[A Communication to the Manchester Photographic Society.]

It was my great good fortune to be very intimately acquainted for many years, and until the time of his death, with a gentleman who a long time ago, I think it was early in the forties, acted as Clerk of the Works for Mr. Brunel during the building of the first tubular bridge the great engineer erected, the one at Chepstow, and my friend was probably the first man to use photography as a means of reporting progress of work.

During the time the construction was going on, a young man, one of Brunel's gentlemen apprentices, was sent down, armed with a letter of advice and instruction by Brunel of most admirable character. From this letter I am able to give an extract that photographers as well as engineers may take a lesson from:—

"You will take," he said, "particular care to enter nothing but facts in your journal, and with this you must learn to understand what is meant by a fact. If you yourself measure anything, or see anything, you may state the result as a fact within your own knowledge, taking great care to be accurate in your measurements, and to make sure of what you think you see. If you are told anything by another person, or if the measurement is made by another person, however accurate or credible he may be, and even more competent than yourself to ascertain the fact, you can only state as a fact that you were told so and so, or that such a measurement was made by such a person. What you do not give in your own journal, therefore, as a fact of your own observation, you must always give only as said to be, and, if possible, give your authority.

"Next in value to accuracy of statement is extent of observation. It is of great importance to observe and record everything. For instance, the time occupied in drilling holes under every variety of circumstances, such as the dimensions of the plates, size of holes, liquid used, whether the plate be held firmly and perfectly steady or not, temperature, &c."

I think it would scarcely be possible to find better instruction to lay before the photographer, who is always face to face with extraordinary and ever varying phenomena, than is contained in this advice to a young engineer, and I should in any communications I may ever make to this Society wish to be as particular as to a fact as Mr. Brunel advised his pupil to be, and also that I should not be afraid to record everything, even though my observation may have been made and recorded before. On such a basis have I gone in this little paper on odds-and-ends. I have recorded trivial observations, and no doubt everything I have seen has been observed by most photographers before. So it must be; but as a teacher may often learn something in instructing an ignorant child, so may the most learned of us be instructed by those less experienced and of far less knowledge than ourselves.

Some of the work I have done during the past summer has been for the stereoscope, and though Mr. Pollitt has to give us a paper to-

night on stereoscopic photography, I dare say what I have to record will not clash in any great measure with what so experienced and so excellent a photographer will have to tell us.

My "stereographs" (if the word which it was attempted to naturalise about twenty-five years ago is still intelligible) have been taken in three ways: first, with an ordinary stereoscopic camera and twin lenses of about four and a half inch focus; secondly, with a quarter-plate camera, the pictures being taken upright, and the lateral movement being given by the legs of the tripod being moved in a given direction one after the other; and, thirdly, with the same camera used with a special triangle, in which is cut a straight slot about four inches long, the views being taken with the camera first held at one end of the slot and then at the other. So far as I can see the results of all three methods are the same in the stereoscope, and it is immaterial whether the camera be moved four or fourteen inches, except that in the latter case, I think, but have not had examples enough to be sure, the stereoscopic focus is lengthened. There is another difference, that of size, the two quarter-plate pictures giving an admirable size of view for the stereoscope, and one much superior to a pair of three and a quarter inch square pictures.

I have also taken stereographs by three different plans: first on glass, second on paper, third with one picture on glass and one on paper. The latter course was adopted in Norway for the sake of lessening the weight of my luggage, and because, however successful paper might be, I must have one glass picture of each view for the sake of obtaining a transparency from it. Of the two pictures on glass, taken with the twin lenses, nothing need be said except that though, of course, developed together, they never develop alike; one always commences a little before the other, and goes on a little faster. Probably this arises from the fact that the film is not quite of uniform thickness.

Of views on paper I have a few examples which probably would be passed, even by most photographers, without observation, but in which grain is very obvious when the view is critically examined; but it is a curious fact that detail in a photograph is shown with a distinctness in the stereoscope which even "the fierce light that beats upon the screen" (to jumble Lord Tennyson) and the enlargement of the magic lantern does not discover. This is shown in a view of the village of Buerbro on the Hardanger Fjord. In the stereoscope the village is plainly to be seen in the distance, between the two great masses of rock, but the lantern fails to reveal the houses in anything like the same distinctness.

Of the third plan, paper and glass, I have several examples, and very fair ones, the grain having almost, though not entirely, disappeared. The pictures, however, are very unequal in the amount of detail shown, glass taking the palm in a very marked degree. The two pictures, however, when united in the instrument are almost as satisfactory as two glass ones would be. This assertion brings me to record another "fact," namely, that two very unequal pictures in the matter of printing or toning unite in the stereoscope with perfect effect. Of this I have one or two examples where a very light picture is mounted with a very dark one, but quite a satisfactory stereograph has resulted, nay, in some cases, I am inclined to think rather a better one than two fully and equally printed ones would have made.

There is one serious disadvantage in taking views for the stereoscope with only one lens, and that is, that the light and shade may vary considerably between the first and second, or if figures are in the picture, they will certainly move between the two. I have two or three examples of this where pictures, otherwise good, have been to some extent spoiled by the movement of figures, and one, that of the Buerbro Glacier, where the stream issuing from the icy cave bothers the observer by refusing to focus properly.

Since writing the above, a friend of very long experience in stereoscopic work tells me that if the camera is moved more than two and a half or three inches, figures and other objects in the foreground are much dwarfed in appearance when seen in the stereoscope, and he points out to me that one of my pictures, where I remember the movement to have been about eight inches, is an illustration of this; it is also an illustration of another fault, mentioned before, for Mr. Muth, who sat as my figure, moved his position considerably between the two exposures.

By all means, then, let twin lenses be used if the best pictures are to result.

I should like to see a half size camera, or perhaps $7\frac{1}{2} \times 5$, which could be used in the following ways:—1. As a camera to take the full size views (half-plate or $7\frac{1}{2} \times 5$ as the case might be); 2. In which another front carrying two lenses might be put, and a division between them for stereoscopic purposes.

It is generally known, but not universally, I think, that it is possible to see stereoscopically without a stereoscope. To do this it is necessary that each eye should be directed to only one of the two

pictures, and the two should combine in the brain just as the two objects on the two retinæ are combined in ordinary vision. It is not easy to do this at first, but a little practice will enable any one to acquire the stereoscopic faculty if he think it worth acquiring.

Let the stereograph be brought very near the eyes (it is advisable to select as markedly stereoscopic a subject as possible), and two indistinct pictures will be seen by each eye. Then move the stereograph slowly away from the eyes, and by-and-by, when it is about eighteen inches distant, after trying again and again, it will be observed that the four pictures have become three, but they are still out of focus. Then, by moving the view a little further from the eyes, focus will be obtained, and the centre picture will be as stereoscopic as though special lenses had been used. The only "fact" to record in this is, that the focus is lengthened at the moment that the stereoscopic effect is obtained. The other two pictures which are in view, one on each side of the stereoscopic one, must of course be disregarded, or they may be cut off by holding a card against the nose.

Having acquired this stereoscopic faculty, and finding that it could be exercised at considerable distance from the stereo slide, it struck me that if one could have the two pictures thrown on the lantern screen a very grand picture would be observed when the two were united in stereoscopic fashion. I therefore got Mr. Pollitt to make me a single lantern transparency, on which were both the right and the left eye pictures, and these two I projected on the screen, of course, side by side. The transparency is markedly stereoscopic when "squinted" at, if I may use that incorrect expression; but after many trials I decided that the projected picture, for a reason I cannot explain, was not so. There is considerable difficulty in observing the projected slide at all, for if you stand at either side of the lantern the perspective view of the screen gives two pictures differing in size, and which, therefore, will not coalesce; and even when you station yourself on the line of the lens, that is, directly above or below it, it is difficult to make the two pictures superimpose one another, and when at last you find the knack of doing it, stereoscopic effect is wanting. My impression is that whether you are above the lantern or below it (and you must be one or the other to get on the same line) the perspective difficulty comes in to spoil the effect; and if this is so, the centre of the lantern itself is the only point from which the view could be properly seen, and we cannot very well get there seeing that we are not salamanders.

So much for stereographs.

ABEL HEYWOOD, JUN.

(To be continued.)

CONTINENTAL PHOTOGRAPHY.

[Translations and Abridgments.]

THE VERSAILLES PHOTOGRAPHIC SOCIETY.

A FEW years ago a photographic society was established at Versailles, the seat of government of the French nation. M. Dutilleul is the President of the Society, which publishes reports of its proceedings in the only photographic journal in the world printed by lithography; the title of its journal is the *Bulletin de la Société Versaillaise de Photographie*, and it is printed by Messrs. Cerf et Fils, 59, Rue Duplessis, in that city. The Secretary to the Society is M. R. Gast, 11, Rue St. Victoire, Versailles. The number before us contains an article by the President about black prints, with the papers of the Compagnie de l'Autocopiste. In their process the image is printed upon parchment paper covered with bichromated gelatine. When the portions of the image not acted upon by light are dissolved off, the sheet is dried, then wetted again and placed on the press; it is next inked in the ordinary way with a roller, and copies are printed off. Special papers are made by the Company for the work. After the paper is sensitised with bichromate of potash it is placed to dry upon a sheet of glass dusted with French chalk. The same number of the journal contains an article on Eastman's paper for enlarging purposes; it also contains a memoir upon Balagny's films, and a paper upon the reproduction of engravings by photography. The last page of the *Bulletin* has the lithographed signatures of the President, and of the Treasurer, M. Gavin.

THE UTILISATION OF PINHOLE PHOTOGRAPHS.

An article by M. G. Ruckert in *L'Amateur Photographe* speaks of the photographs taken by means of a pinhole instead of lens, exhibited before the Photographic Society of France in 1866, and remarks that the system may be useful for some special purposes, such for instance as that of including an angle of view greater than any lens will give. M. Pribourg has made experiments and satisfied himself that the images given by pinhole cameras are geometrically true. Captain Colson, of the engineers, thinks that pinhole cameras can be utilised in topography; exact geometrical projections in perspective taken with

two cameras from different points of view afford a means of accurately measuring heights and distances. The paper is illustrated with a photo-lithograph of the Cathedral of Notre Dame, of much better quality than those usually exhibited as specimens of work done with pinhole cameras.

ICE LENSES.

The London correspondent of *Le Moniteur de la Photographie* writes to that journal that in the middle of the winter which has just elapsed a student made a lens of ice, with which he lit the pipes of some of the skaters on the Serpentine by means of the solar rays, an experiment, he says, which was first performed in the Polar regions by Dr. Scoresby, to the great astonishment of the sailors, for they could not understand why the ice did not freeze the beams of the sun. We may remark that Professor Tyndall at times would set fire, at the Royal Institution, to a little heap of gunpowder with rays from the electric arc concentrated upon the powder by means of a lens of ice. His explanation was that, although ice absorbs rays of certain wave-lengths, and is gradually melted thereby, other waves it does not absorb, and these latter produce the heating effect at the focus of the lens. It is wholly a question of the relative motions of the molecules of frozen water and the motions of the waves of light; when there is discord between the two, the discordant waves pass through the ice without absorption.

ON RED AND PURPLE CHLORIDE, BROMIDE, AND IODIDE OF SILVER; ON HELIOCHROMY, AND ON THE LATENT PHOTOGRAPHIC IMAGE.

I.

In this series of papers it will be my object to show: (1.) That chlorine, bromine, and iodine are capable of forming compounds with silver exhibiting varied and beautiful colouration, peach-blossom, rose, purple, and black. That these compounds (except under the influence of light) possess great stability; that they may be obtained by purely chemical means, and in the entire absence of light. (2.) That of these substances the red chloride shows a tendency to the reproduction of colours. It seems not improbable that the material of the infinitesimally thin films obtained by Becquerel, Niepce de St. Victor, Poitevin, and others in their experiments on heliochromy may be the red chloride. (3.) That these substances, formed by purely chemical means, constitute the actual material of the latent or invisible photographic image, which material may now be obtained in the laboratory without the aid of light and in any desired quantity. They also form part of the visible product resulting from the action of light on the silver haloids.

For more than a generation past the nature of the latent photographic image, that which forms the basis of development, has been in dispute. Two theories have been maintained. According to the one, the first effect produced by light is simply a physical change, predisposing the elements of the silver haloid to dissociation, so that when a reducing agent is applied the molecules so affected yield more quickly to its influence. According to the other theory, the invisible image is formed of a subsalt (subchloride, &c.). Observations which I published many years ago led me strongly to the first-mentioned of these theories. But of late years, results have been obtained not easily reconcilable with it. On the other hand, the theory that the latent image is formed of subsalt is opposed to striking facts. Silver subchloride, for example, is an unstable substance, quickly destroyed by dilute nitric acid. But I have formed a latent image on silver chloride, and after exposing it for five minutes to the action of strong nitric acid (s.g. 1.36) have developed the image without difficulty; the same with silver bromide. Evidently these images, which so strongly resisted the action of undiluted acid, could not be formed of simple subchloride and subbromide of silver, substances quickly destroyed by it.

In the desire to find a satisfactory explanation of the nature of the image based on adequate chemical proof, I have devoted nearly three years of laboratory work to this and to closely allied subjects. I am led to the conclusion that neither of the older views is correct. A truer theory seems to be deducible from the result of some experiments which I published in 1885, to the effect that the silver haloids were capable of uniting with certain other substances, much in the same way that alumina forms lakes. When a silver haloid was precipitated in the presence of certain colouring matters they combined with it, and though soluble in water, they could not be subsequently washed out. They had formed a somewhat stable compound, although the proportion of colouring matter was very small in comparison with the haloid; evidently much too small to represent a stoichiometrical composition. Now I find that a silver haloid may in the same way unite with a certain proportion of its own subsalt, which, by this union, quite loses its characteristic instability and forms a compound of great permanence.

Another explanation is possible; the subsalt may combine with the normal salt, not in the manner above described, but in stoichiometrical proportion, and this compound may be diffused through ordinary silver haloid. I have not been able to find any reaction decisive between

these explanations,* but the general behaviour of the substance seems rather to indicate the first named explanation as the true one. When the red chloride, for example, has been boiled with dilute nitric acid for a few moments to eliminate any uncombined subchloride, the proportion of subchloride left has never exceeded eight or nine per cent. in over thirty specimens analysed. If we took this to represent a compound in equivalent proportions, we should have to suppose the union of at least twenty equivalents of AgCl with one of Ag_2Cl , which is improbable. If we suppose that these coloured substances containing from less than one-half per cent. up to eight or nine per cent. of Ag_2Cl consist of a compound of one equivalent of subchloride united to a small number of equivalents of normal chloride, mixed mechanically with a large quantity of normal chloride, then it would be improbable that specimens could not be obtained containing a larger proportion of this compound and consequently of Ag_2Cl , but, as already said, specimens containing more than nine per cent. after thorough treatment with nitric acid to remove the uncombined subchloride I have never obtained; generally the amount is less.

Even when silver chloride, bromide, or iodide contains as little as one-half of one per cent. of subsalt combined, its properties are greatly changed. It has a strong colouration, and its behaviour to light is altered. Even a much less quantity, one inappreciable to analysis, is capable of affecting both the colour and the behaviour to light. It is one of these latter forms of this substance that constitutes the actual material of the latent photographic image. Adequate proof of this will be given in the second part of this paper.

RED SILVER CHLORIDE.

Of the three haloids, the chlorine salt is the most interesting, because of its relations to heliochromy; it is also the most stable of the three compounds, and exhibits, perhaps, a finer variety of colouration, though the bromide and iodide are also obtainable of very beautiful tints. The chloride shows all the warm shades from white to black through the following gradations: white, pale flesh colour, pale pink, rose colour, copper colour, red-purple, dark chocolate, black.

These compounds are obtained in an endless variety of ways: by chlorising metallic silver; by acting on normal chloride with reducing agents; by partly reducing silver oxide or silver carbonate by heat and treating with HCl ; by forming suboxide or a subsalt of silver and treating with HCl , followed by nitric acid; by acting on subchloride with nitric acid or an alkaline hypochlorite, &c.; by attacking almost any soluble salt of silver with ferrous, manganous, or chromous oxide, &c., followed by HCl ; by reducing silver citrate by hydrogen and treating it with HCl ; by treating a soluble silver salt or almost any silver solution with potash or soda, and almost any reducing agent, cane sugar, milk sugar, glucose, dextrine, aldehyde, alcohol, &c., and supersaturating with HCl ; there is no organic easily oxidisable substance that I have tried that has failed to give this reaction. Also almost any salt of silver exposed to light, treated with HCl and then with hot strong nitric acid, yields it. Almost any of these classes represents a long range of reactions, each susceptible of endless variation. In fact, the more the matter is studied, the more extended the range of reactions is found to be that give rise to the formation of this substance. To show how slight an influence will lead to the production of red chloride instead of white; if freshly precipitated argentic oxide is mixed for a few moments with starch or tragacanth paste, and is then treated with HCl , the result is, not white, but pink, silver chloride. Even raw starch flour mixed with silver oxide will, in a few moments, cause it to give a pale flesh coloured chloride with HCl . Boiled starch or tragacanth paste does this more quickly and acts more strongly, even in the cold, and still more if heat is applied.

Although red is probably the most characteristic colour of this substance, so that I have spoken of it above as red chloride, nevertheless this hardly seems a proper name for a substance that is often purple, chocolate, or black, sometimes brown or even ochreous, sometimes lavender or bluish, and is probably capable of assuming every colour of the spectrum. To call it argento-argentic chloride would infer a stoichiometrical composition that, as already mentioned, seems very uncertain, too much so to serve as the basis of the name. Therefore, and as these substances have been hitherto seen only in the impure form in which they are produced by the continued action of light on the normal salts, it might be convenient to call them photosalts, photochloride, photobromide, and photoiodide instead of red or coloured chloride, &c., and thus to avoid the inexactness of applying the term red chloride to a substance exhibiting many other colours.

Photochloride by Action of Alkaline Hypochlorites.—Black or purple-black chloride is easily obtained by the action of an alkaline hypochlorite on finely divided silver, such as obtained by reduction in the wet way. Commercial sodium hypochlorite may be used to act on it. It is to be poured over the silver, and after standing a few minutes, is to be replaced with fresh. After an hour or two this is again to be replaced with a new portion, which is to be allowed to act half an hour to insure the total conversion of the silver. The product varies somewhat in colour, is sometimes black, oftener purple-black. If the treatment with hypo-

chlorite has been thorough, strong cold nitric acid of 1.36 s.g. extracts from it no silver. This reaction with nitric acid is important, as it shows that not only metallic silver was not present, but that the product contained absolutely no uncombined subchloride. For if any were present it would instantly be decomposed by the acid, in which one-half of its silver would dissolve. The action, therefore, appears to take place in this way. First subchloride is formed, part of this is further chlorised into normal chloride which at once combines with other subchloride, thus taking it out of the further immediate action of the hypochlorite, and this goes on until an equilibrium is reached, and neither metallic silver nor uncombined subchloride is left, as is proved by the action of nitric acid. Alkaline hypochlorite, as will presently be shown, attacks uncombined subchloride very rapidly, the combined very slowly; by many days' contact the quantity of combined subchloride is gradually reduced.

Prolonged treatment with hot strong nitric acid destroys all the varieties of photochloride. The time needed varies a good deal. A specimen of that obtained with hypochlorite required twenty-five hours' heating with acid of 1.36 in a water bath at 212° Fahr. to bring it to the condition of white normal chloride. Considering that cold dilute nitric acid instantly destroys freshly precipitated argentous chloride in the free state, this long resistance to strong acid at the temperature of boiling water must be considered most remarkable.

When the red or photochloride is formed with the aid of a ferrous salt or ferrous oxide, I prefer to boil the product with dilute HCl to get rid of the last traces of iron, after a preliminary treatment with hot dilute nitric acid has removed silver and uncombined subchloride. The photochloride will sometimes even resist boiling aqua regia for a time.

Protected from light, photochloride is perfectly stable. Specimens obtained eighteen months ago appear to be quite unchanged.

When treated with ammonia, it is far more slowly attacked than the normal. The ammonia dissolves the normal chloride only. The union between the two must therefore be broken up, and this takes place slowly. The first action of the ammonia is to change the red or purple colour to greenish black and then to slowly dissolve out silver chloride. Hours are required even with a large excess of ammonia. Whilst this is going on, if the ammonia is poured off and replaced with nitric acid, the original colour reappears. If the action is continued sufficiently long, silver only remains and dissolves readily in nitric acid. A little short of this, treatment with nitric acid leaves a black residue of dark chloride mixed with metallic silver. The dark chloride being insoluble in any acid, has led to some strange mistakes in a similar reaction which occurs in treating with ammonia silver chloride that has been exposed to the light. Even a theory has been had recourse to of a "passive condition" of silver. This passive silver is simply black chloride.

A specimen of purple-black chloride was treated with warm strong aqua regia until whitened by conversion of the subchloride to normal. By this treatment 2.563 grammes of photochloride gained nine milligrammes, indicating the presence of two and a half per cent. of subchloride, or more exactly

Subchloride	2.49
Normal chloride	97.51

This is not to be taken in any sense as representing a constant composition. The proportion of subchloride varies between certain limits, not only according to the method of preparation used but independently of it. Another specimen of black chloride formed with hypochlorite gave figures that indicated a content of less than half of one per cent. of subchloride.

Photochloride by Reduction of Normal Chloride.—This is an excellent means of obtaining red chloride. The white chloride is to be dissolved in ammonia and ferrous sulphate added, producing an intensely black precipitate. After standing a minute, the mixture is to be treated with dilute sulphuric acid until it shows a strong acid reaction.

The precipitate is to be first well washed by decantation, then boiled first with dilute nitric, then after washing with dilute hydrochloric acid, which must, of course, be thoroughly washed out.

The product obtained in this way is often of singular beauty. It might easily be taken for metallic copper. Sometimes it is as rich and bright in colour as the copper obtained by electric deposition. Every one knows the richness and brilliancy of that form of copper, and I have seen it fully equalled by this silver salt.

The beauty of the colour depends always on the thorough removal of any metallic silver that may be present, and still more on getting rid of every trace of iron. The boiling with dilute hydrochloric acid should be continued until, after thorough washing, a fresh treatment extracts no more and the acid remains colourless in presence of alkaline sulphocyanide.

Instead of an ammoniacal solution of silver chloride, we may make a solution of any other silver salt in ammonia and reduce it in the manner just described with ferrous sulphate. But in this case hydrochloric acid must be used instead of sulphuric after the reduction. This single reaction includes an almost endless variety of methods. The acid with which the silver was originally combined seems to be not without influence on the result; in some cases, for example, with arseniate and molybdate, the action of coloured light on the red chloride seems to be

* Silver chloride may be dissolved out by hot solutions of sodium or ammonium chloride, but the subchloride is at the same time decomposed. See beyond under head of "Reactions."

somewhat modified. Silver phosphate on account of the ease with which it suffers reduction is very well adapted for this treatment.

Photochloride by Partial Reduction of Oxide by Heat, and Treatment with H Cl.—This method has the advantage of avoiding all admixture of foreign substances, the last traces of which are very hard to get rid of, and seem to exert an effect on the colour disproportionate to their quantity. Accordingly the photochloride obtained in this way is very beautiful, the shades are from pink to copper red, and a tint resembling burnt carmine.

Heat may be applied to the oxide in either of two ways, long continued heat at 212° Fahr., or near it; or the change may be effected by roasting.

When slow heat is to be applied care must be taken that the oxide does not carbonate itself, which it easily does superficially; this is an objection because the carbonate, under these circumstances, yields white chloride with which the other becomes mixed. The air of a drying oven heated by a gas burner is especially bad in this respect. I have seen a surface of oxide form a coat of yellow carbonate in a few hours in this way. (Most oxide that has been kept some time will effervesce briskly with an acid.) The method is uncertain, sometimes giving strongly coloured products and sometimes pale pink.

The oxide may be roasted in a shallow, flat-bottomed porcelain basin. With a very moderate heat it changes from brown to black. When this is thoroughly accomplished and before grey reduction sets in, the oxide is to be treated with H Cl. If this be done in the basin itself after cooling and without disturbing the position of the oxide, a curious variety of tints will be noticeable, depending upon slight differences in the heat affecting different portions.

M. CAREY LEA.

(To be continued.)

HOW TO PREPARE FOR GOING OUT WITH THE CAMERA.

WHERE to go with the camera, with a fair prospect of finding suitable subjects to photograph, is a question more often asked than answered. This is especially the case when the time is limited to an afternoon, or at most a day. Each year seems to curtail the number of places, the ever-extending operations of the builder destroying, bit by bit, the picturesque surroundings of this overgrown London. The season for camera outings is now coming on, and a reliable list of places to go to would be an unmistakable boon. I say *reliable* advisedly, for the extraordinary ideas some people have of the requirements of photographers are most misleading and disappointing. I have been told by an enthusiastic lover of nature, that such and such a place was simply magnificent, no fear of lack of subject, take plenty of plates and go and see for yourself. I've been confiding, and have been to see for myself, and I've taken plenty of plates; moreover, I've brought them home again unused.

There are, however, few places that something cannot be squeezed out of in the way of a picture, but when one expects to find a plethora and discovers barrenness it is not conducive to happiness, especially if the journey has been long. The question is, How can we get plenty of reliable information? I would suggest as one way out of the difficulty, that any landscape photographer or painter conversant with photography who is desirous of benefiting his brethren, should send in the names of localities within easy reach of London, with an accompanying description in plain language of the sort of subjects to be found in them, to the *Honorary Secretary of the Photographic Club, Anderton's Hotel, Fleet-street*, who, from such information, would be enabled to compile a useful and reliable directory for reference, not only for the members of the Club but for any friends who may honour the Club as visitors.

If access was obtainable to a carefully written list of places with a terse description of the material there to be found, one could decide at once if such a locality would meet his requirements, and be prepared for the kind of work that lay before him, and select the sort of plates that would be best adapted for it. If those interested in the matter would fill up a form similar to this sketched below and forward it, it would be a great step towards such a desirable consummation.

Place or Locality.	Description.	Means of Access.	Nearest Railway Station.	Hotel.	Other Information.

With regard to the "description," it should be remarked if it is architectural or landscape. If architectural, whether cottages, old buildings, ruins, or ecclesiastical structures. If landscape, whether water, trees, open landscape, or studies. "Other information" would include the distance apart of interesting bits and the amount of walking or riding that would be necessary, and the facility with which vehicles can be procured. General information of this sort is invaluable to those who go to such places for the first time, and would add vastly to the comfort of those who go on a photographic outing of limited duration. The chief point is to

have such information perfectly reliable; and to be so, the giver must be thoroughly acquainted with the requirements of photography. It must not be for a moment imagined that the information is expected to fix on what a man is to photograph or pass by (for every photographer worthy the name will select his views according to his own ideas, and not servilely imitate another), but merely indicate such places where, to the informant's ideas, picturesque subjects are to be found.

EDWARD DUNMORE.

IMPORTANT INVESTIGATIONS IN THE SALTS OF SILVER.

As will be seen from a leading article, and also from the first portion of a communication from Mr. M. Carey Lea, which will be found in another column, this gentleman has entered upon a most important field of investigation. A concise synopsis of his discoveries is given in the last number of *Nature*, as follows:—

"In the May number of the *American Journal of Science* will be found a paper by Mr. Carey Lea, of Philadelphia, in which are described a remarkable series of salts of silver, which the author is attempting to make use of in obtaining photographs of objects in their natural colours. It is first shown, by an exhaustive series of experiments, that when light acts upon ordinary silver chloride, Ag Cl, in presence of hydrochloric acid, the darkening is due to the formation of a small quantity of subchloride, Ag₂ Cl, which enters into combination with the unaltered silver chloride to form a reddish compound of a nature similar to that of a 'lake.' This red chloride of silver is termed photochloride, and is found to be, unlike subchloride, unattacked by cold strong nitric acid. After a certain amount of this substance is formed, the action of light appears to cease—a phenomenon which has been frequently noted by other observers. Successful efforts were then made to prepare photochlorides, bromides, and iodides of this nature, and a full description of the very numerous methods and analyses is given in the memoir. The startling fact was discovered that all varieties of tints from one end of the spectrum to the other could be obtained under suitable conditions. Normally, the photochloride of silver is red, even one-half per cent. giving to ordinary silver chloride a strong colouration; but on exposure to diffused sunlight it quickly changes to purple. On addition of mercuric silver chloride it becomes grey, potassium bromide changes it to a permanent lilac, potassium iodide to a bluish tint, while a mixture of potassium chlorate and hydrochloric acid causes it to pass through pink and flesh colour to white. Heat, on the contrary, causes it to retake its red colouration, and on exposure to various parts of the spectrum it affects lovely shades of the most varied hues. The important observation was made that, in presence of small quantities of lead or zinc chloride, white light (which darkens the pure photochloride) bleaches it, thus producing white in those portions of the image which ought to be white; and it was also found that the addition of a little sodium salicylate enhances the sensitiveness threefold. The experiments are being continued, and appear likely to lead to important results in chromo-photography."

WHITENING GELATINE FERROTYPES WITH BICHLORIDE OF MERCURY.

THE effects of applying a bichloride of mercury solution to photographic silver deposits are well known to all practical photographers, as mercuric chloride has in various forms and for various purposes for a long time been employed in photographic laboratories. With it we have made "magic" photographs, have bleached out prints for engraving purposes, have reduced negatives, chlorinated the deposit previous to redevelopment, and have given to collodion positives those beautiful whites, in the more developed parts, which were so greatly admired by the public.

The long-wished-for solution of the problem of making gelatine positive or ferrotype plates had hardly been accomplished, when we find one of Germany's renowned emulsionists proposing improvements on the rather unsatisfactory tones of the pictures, made upon them, by whitening the deposit with a solution of mercury. Gelatine ferrotypes seem to have become very popular in Germany, and with the demand for them naturally arose the desire to improve their appearance. Dr. Schleussner tells us that this may be done with a weak solution of the bichloride of mercury. The method of working is similar to other operations of this kind; in fact, there is nothing to be done to the plate, except to leave it in the solution until the picture assumes the desired white appearance.

The peculiar bleaching effect of bichloride of mercury upon a collodion positive was first observed by Scott Archer, and dates back as far as 1850, at which time these pictures were first introduced in Great Britain, and before any attempts with collodion had been made in America. He recommended the use of a saturated solution of the bichloride in hydrochloric acid, one part of the solution being diluted with six parts of water. After the picture was fixed and well washed, this solution was applied. The positive image was first darkened, but it speedily began to whiten, and a delicate, beautiful, white picture was brought out. The method described by Archer may be applied to gelatine ferrotypes, although it is advisable to reduce the strength of the solution considerably, using, perhaps, instead of six parts of water, suggested by Archer, as much as twelve parts. As one of the first conditions for a good gelatine ferrotype plate is an extremely thin film of an emulsion, rich in silver, with a

strongly adhesive gelatine, the reaction takes place quickly and is completed with a solution in the proportion 1:100 in about two minutes. Before the mercurial solution is applied, the plate must be perfectly freed from hyposulphite of soda, an operation which, on account of the thin film, requires also but little time.

The fine appearance of the pictures, the absence of difficulties when making them, the rapidity of exposure, all warrant a general adoption of the process in a certain photographic sphere, and there is nothing seriously to be considered doubtful except their permanency.

Since we have become familiar with the working of gelatine films, the application of mercurial salts has been more or less condemned, justly, perhaps, in some cases, but in others without the least reasonable foundation. Negatives intensified with the salts of mercury have stood a test of several years; why may not a whitened positive, if properly made, be equally permanent?

When mercuric chloride is brought into contact with metallic silver, the latter is converted into chloride at the sacrifice of some chlorine of the mercuric salt, reducing it to mercurous chloride (calomel), making, in all probability, the substance of the white film a mixture of the two chlorides.

Silver chloride, as we all know, is sensitive to light, and so is calomel, especially when exposed at an elevated temperature under the influence of a moist atmosphere. Hence we must infer that the white deposit cannot be permanent, and that it is liable to change colour in a very short time. In the case of "alabasterine" collodion positives, it was not always found to do so; glass positives whitened with mercury, made thirty years ago, have retained their whiteness to the present day as well as a Daguerreotype; while others again, and a greater number, have changed.

To explain these singular facts we must consider the mode of preparing the solution of mercuric chloride. Many operators were, in the early days, in the habit of using instead of hydrochloric acid as a solvent for the mercuric salt a solution of chloride of ammonium, by which stability of the whitened deposit was established. If, in course of the operation, ammonia was set free, which was by no means unlikely, mercurous-ammonium-chloride, or white precipitate would necessarily result. This precipitate is almost perfectly white; it is much whiter than calomel, which is rather of a yellowish tint, is not affected by light to any marked degree, and will stand rather a high temperature before it decomposes.

The permanency of photographic pictures can be judged of only after a lapse of time, and a mercurialised gelatine positive, with all its original brilliant whiteness, must be subjected to the same test with all other photographs. Whether a ferrotype possesses the same merits and has the same value as a silver print, or whether permanency is for these a *conditio sine qua non*, or otherwise, we will not attempt to decide. Mercuric chloride gives beautiful effects to gelatine ferrotypes, and, if carefully made, these ferrotypes will retain their beauty for a reasonable time. Let us not decry their beauties because there is a doubt of their permanence, but enjoy them rather while they remain.

IMPROVEMENTS IN CHANGING BOXES FOR PHOTOGRAPHIC CAMERAS.

No. 8329. ARTHUR SAMUEL NEWMAN, 87, Evershot-road, Finsbury Park, Middlesex.—*June 24, 1886.*

This invention has for its object to provide a means whereby the plates or "films" used in a camera can be readily changed without having to close or remove the changing box, and is more simple and effective than changing boxes as hitherto constructed.

For this purpose I construct the changing box, holding any suitable number of plates, with two slits or apertures at the top of the box, one at the back and the other at the front. Over these slits a hood or covering is mounted of sufficient size to freely contain a plate, this hood or covering being formed of any flexible light-tight material (or it may be a bellows), and is securely fixed on the box.

The plates or "films" are arranged in the box all facing the front, and in order to remove a plate on which a photograph has been taken and bring another plate into focus without removing the changing box or closing the shutter thereof, a cranked lever is provided (one end of which is outside of the box), and the other end connected to a wire or rod reaching across the box, and caused to travel (by the operator moving the lever) in a parallel direction near the front of the box, exactly in the place where the front plate is situated, and, rising beneath it, causes the plate to be raised into the dark hood or covering, and enables the operator to grasp it, and draw it quite out, and insert it again through the back slit or aperture behind the other plates (a spring mounted

upon the back of the box keeps all the plates pressed forward), a fresh plate being thus presented ready for use and in exactly the same focus, the film of each succeeding plate being in the identical position occupied by the last previous one.

In order to effect this object, I mount the plates in metal carriers, which hold them partly along the foot and each side at the top, where the metal carrier is turned over or appears in front; corresponding grooves or recesses are provided in the inside of the front of the box, so that the front plate or "film" will always become the bearing surface, which will lie against a bearing specially provided in the box, which latter bearing is recessed or hollowed out behind so as to allow for the edge of the metal carrier where different thicknesses of plates or "films" are used.

Instead of the cranked lever and rod before referred to, other means can be adapted for raising the plate in the first instance, such as by means of rack-work, an endless band, a lever and screw, or other suitable means.

The whole apparatus forms a changing box of the same sized sectional area as the camera to which it is fitted.

This changing box will also work equally well on its side.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. William England, Vice-President, occupied the chair.

Mr. T. SAMUELS exhibited a small camera with twelve plates which could be changed by means of a little closed bag at the back, which bag the hands of the operator did not enter; the plates were four and a quarter inches square and placed in metal sheaths. He also exhibited a half-plate camera made on the same principle, with improvements; likewise a quarter-plate camera. The cameras had no rising or falling fronts.

Mr. FRIESE GREENE suggested that the addition of an indicator, to denote the number of plates exposed, would be useful.

Mr. T. SEBASTIAN DAVIS said that there was a somewhat similar camera in the market in which the view could be seen at the time of making an exposure, and that was an advantage.

The CHAIRMAN remarked that it was a camera which could be used in a street without attracting public attention.

Sir D. SALOMONS, Bart., said that for most distances small lenses gave nearly all the view in focus, but that if some objects were exceptionally near the lens the proper adjustment could easily be made by means of a simple calculation.

Mr. F. W. EDWARDS then gave a demonstration of the platinum process, similar to one recently described in these pages.

Mr. DAVIS said that at exhibitions platinotype and silver prints were found to advantageously set off each other when placed side by side.

The CHAIRMAN exhibited some platinotype prints of excellent quality, portraits included, upon reputed silk, taken by his son Louis.

Mr. Meudelssohn said that it was actually a fine ambrie, resembling silk, and that Chinese silk would be the best for the process.

The proceedings then closed.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday night, May 19, at a meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. H. M. Smith presided.

Mr. Herbert Starnes exhibited a tin holder for use when developing collodion-bromide lantern slides to avoid soiling the fingers; it was a kind of little shovel with corners turned up to prevent the plate slipping off.

The HON. SECRETARY produced some of his results in the taking of paper negatives; he felt sure that paper negative processes would make headway, because of the saving of weight in the field; the only drawback was the necessity for making the negatives translucent by oiling or otherwise.

The CHAIRMAN thought that persons with roller slides would be tempted to go in for quantity rather than quality.

Mr. W. M. ASHMAN said that paper negatives offered great facilities for development. When Mr. Belas returned from Rome with a long strip of negatives he induced Mr. Cobb to walk off with one end of the strip and pull it across the room as the paper came out of the developing dish, and after pulling the strip thus three times through the developer the string of pictures was finished so far as development was concerned.

Mr. F. W. COX asked if the results were not flatter with paper negatives than with the best results upon glass. He had never seen a paper negative which gave good stereoscopic effect in a resulting print.

Mr. ASHMAN read a letter from Mr. Spurge apologising for absence from a recent meeting; he had obtained an appointment as chemical assistant to Mr. Campbell Brown, of University College, Liverpool, and on the night of the meeting had been engaged until a late hour with Mr. Van der Weyde over electric lighting matters.

Mr. W. E. DEBENHAM called attention to newspaper reports that Mr. W. K. Burton had stated publicly in New York that English photographers were less willing to impart information than those in America; he did not believe that Mr. Burton ever said anything of the kind.

Mr. W. H. HARRISON said that there was a paragraph in Mr. Burton's latest book expressing an altogether different opinion to that attributed to him in New York.

Mr. C. HEINRICH TRINKS read an extract from an article by Mr. Burton in the New York *Photographic Times* expressing opinions at variance with those attributed to him in the reports under notice.

The CHAIRMAN thought that Mr. Beach had made some mistake when reporting Mr. Burton's utterances.

Mr. ASHMAN did not believe that Mr. Burton had said anything of the kind attributed to him.

Mr. H. MOUL asked what was the best class of negative for collotype work.

Mr. DEBENHAM replied that the one which would give the best silver print would do best for collotype work.

Mr. A. L. HENDERSON had received a circular from the printers to the Newcastle Exhibition saying that the exhibits there were to be illustrated by a photo-mechanical process; they had enclosed him a very good specimen of such work. Had any one seen Mr. Hyslop's photographs of the performance at the Criterion Theatre?

Mr. TRINKS had seen them; some of them he considered to be very good indeed, the others were a little blurred.

Mr. MOUL remarked that the said Criterion photographs had been done by Mr. Roberts upon Cadett's plates.

Mr. ASHMAN said that Mr. Hyslop had photographed the performances at the St. James's Theatre.

The CHAIRMAN asked if any one had tried to photograph the Queen during her drive through the City; he had tried in Cheapside, but he failed because she went by at such high speed. He photographed the crowd all right, also pieces of paper blowing about in the air as the procession swept past.

Mr. A. COWAN said that it was the business of a procession to process.

Mr. HENDERSON had on the same day tried to photograph her at Mile End, but she drove past at the rate, he estimated, of nine miles an hour. He used a lens made by Suter.

Mr. COWAN thought that the lens did not suit her.

The Association resolved to hold an outdoor meeting on Whit Monday, May 30, at Chiddlingstone, near Peshurst, Kent, for which a train by the South Eastern Railway leaves London Bridge at thirty-five minutes past nine a.m.

The meeting then broke up.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held on Tuesday, the 17th instant, at Myddelton Hall, Islington, N., Mr. J. Traill Taylor, President, in the chair, Messrs. C. Cusworth, J. G. Hilton, and E. Purton, were elected members of the Society.

Mr. CORNIX exhibited and explained the working of his patent "one back," which was examined with interest.

Mr. C. Cusworth showed a half-plate camera of his own construction.

Mr. A. Mackie exhibited some transparencies on plates coated with the collodion emulsion he had made at the lecture at the previous meeting.

Mr. W. H. WALKER (of the Eastman Company) delivered a lecture explanatory of the principles and working of the Eastman-Walker stripping film. In course of this he described a discovery that had been made by which the expansion of paper when wet was in a large measure obviated. He also described the various operations incident to the manufacture of the films. He was ably aided by Mr. John Jackson, who very skillfully demonstrated the process from the development of a negative to the final stripping, specimens of the work at various stages being handed round.

In reply to Mr. L. Medland, Mr. WALKER said that the films registered 22 by Warnerke's sensitometer.

The thanks of the meeting were voted to Messrs. Walker and Jackson.

Excursions were arranged for Saturday, May 28, to Richmond, and for Whit Monday, May 30, to Chiddlingstone. (London Bridge Station, thirty-five minutes past nine train. Book to Peshurst.)

Next meeting, on Tuesday, June 7, will be a technical meeting. Visitors are invited.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

The usual fortnightly meeting of this Society was held at the Greyhound Hotel on May 11.—Mr. Crosthwaite in the chair.

Some fine platinum pictures by Mr. Payne Jennings were passed round and elicited admiration, the artistic merit of these productions being of the highest standard.

After the usual business an exhibition of lantern slides was made, several members contributing specimens of their work. Mr. Smith, of Great Portland-street, brought a fine selection of slides made by the Woodbury process. Some exquisite collodion transparencies kindly lent by Mr. Gale were also exhibited.

Mr. SMITH explained the principles and working of a special camera designed by him for the production of lantern pictures.

The usual votes of thanks brought the proceedings to a close.

BURY PHOTOGRAPHIC AND ARTS CLUB.

The ordinary monthly meeting of the above Club was held on Wednesday evening, May 18, in the Temperance Hall, Henry-street, Bury.—The President (Mr. F. W. Livsey) in the chair.

The minutes of the previous meeting having been read, were confirmed.

A discussion then arose as to where the places for the outdoor meetings for the ensuing year should be held. It was finally decided that the Council should choose the localities from the following places named by the members at this meeting:—namely, Kirkstall Abbey, Fountains Abbey, Harlestone Craigs, Tabley Park, Speke Hall, Lyne Hall, and Malham.

The Secretary (Mr. C. H. Openshaw) then produced a pneumatic drop shutter, designed by himself and Mr. H. M. Beardon, and made by Mr. S. Hepworth, also some photographs of trains exposed by the same, which were much admired, there being not the slightest sign of movement, though the trains were going at full speed. The shutter itself was also much admired both for the simplicity and speed with which it worked.

The PRESIDENT then produced a photograph (silver print) of Nuttall Hall, near Ramsbottom, the residence of J. G. Lawson, Esq., which had nearly faded out. He said the photograph had been thoroughly washed and mounted with a reliable mountant; it had also been kept in a dry place. He invited the members to open a discussion as to the cause of the fading, which ended in the general opinion being that the mount on which the photograph had been placed contained some impurity.

The meeting then terminated.

PHOTOGRAPHIC SOCIETY OF IRELAND.

OWING to an oversight in the report of the meeting of the above Society which appeared last week, mention was omitted of a camera and new pattern stand which was exhibited by Mr. J. V. Robinson.

The camera is similar to his well-known patent camera, but has an addition of a strut or arm from baseboard to back of camera, this arm being so constructed as to allow of double swing while at the same time rendering the camera perfectly rigid. Considerable interest was shown in the examination of this contrivance.

The camera stand is a folding or portable pattern, consisting of three joints, the lower a folding and the middle a sliding joint. The point of novelty is the method of clamping this middle or sliding joint by a hinged wedge, which is very quickly brought into action or released. It appeared to be the opinion of the meeting that this is a good and effective construction of camera stand.

Correspondence.

COLOURED PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—Like other advances towards a great discovery, the "new departure in coloured photography" lately made by Mr. J. E. Mayall, of 161, New Bond-street, has given a new impulse to the question of "Photography in natural colours." His discovery, whatever its nature, if based on chemical action, is great, because it would be the first successful attempt, so far as we know, at producing chemically a photograph in various colours. The new process of Mr. Mayall, then, bids well to be popular, and we heartily wish him a profitable as well as a scientific success.

Without pretending to understand the nature of Mr. Mayall's discovery, we do not think he gives it out as the looked-for process of photography in natural colours, but we think that if the progress of photography keeps pace with the advance it has made within the last twenty years, the time is not far distant when some such discovery may be made.

Hitherto, we may say we have been working in the *dark*, since the productions of photography are made with *shades*; at no remote date, probably, we may be speaking of lights and colours instead of lights and shades.

At this rudimentary stage of our knowledge on the subject, however, it may not be out of place to indulge in some hypothetical remarks as to the probable nature of a process likely to fulfil our expectations of the eagerly looked-for discovery, in as much as conjectures are the preliminaries of all theories which are to be proved by practice or acquired by empirical researches, and as such conjectures, corrected by vying critics and additional opinions, eventually ripen into the desired result, however indirectly it may come.

It appears to us, therefore, that the ultimate success of photography in natural colours shall consist in the production of a negative in colours complementary to those of the object represented, the natural colours of which shall be reproduced on the print or positive; as, for example, a blue eye would appear on the negative of an orange colour, the carnations would appear green, yellow would appear purple, &c. To give a practical example of this idea: if we take a piece of red glass and look through it at a red-brown colour, the latter will appear of a drab or greyish drab colour, that is, of such a colour as, if mixed up with the same colour as that of the glass, would reproduce the actual brown colour under observation. In fact, the red colour of the glass thus appears subtracted from the sum of colours composing the brown, and, in like manner, each tint of the coloured negative would subtract its own colour from white light, or, to use the expression of physicists, would absorb the rays of its own colour and intercept them, but transmit the rays complementary to it.

Until the nature of the impressed photographic image before development be better understood, it will probably be difficult to arrive at a practical solution of the problem. In our opinion, the agency by which the invisible image is produced is not chemical in its nature; the rival theory, that it is due to a disturbance of the molecules of the iodide of silver, is probably not more correct. Our own idea, which we think is a new one on that subject, is that a peculiar physical disturbance, which we may call vibration, is produced in the waves of light under the existing favourable circumstances, by some complex phenomena taking place in the sudden transmission of the rays of light through several suitable media, which are the air, the sensitive film, and the plate; during which course the rays undergo several refractions and reflections, which disturb the relation of the waves of light under circumstances favourable to the development of actinic force, which receives an uneven distribution over the plate, determined by the reflection of the

rays of light from the object or image to be represented. Actinic force would then be produced in a manner analogous to what takes place in the mechanical development of electricity in amber by friction or by the mere contact of two plates of different metals. The actinic force would then be in a state of tension or inhibition, in the manner of stored-up electricity, ready to develop chemical action under favourable circumstances, as electricity would do. In fact, actinism is a force similar to electricity and both are no doubt interconvertible, such also as heat, motion, and other forces. Moreover, invisible images have been produced by electricity, and further investigation will probably reveal that they may be produced likewise by the agency of other forces, such as heat, friction, magnetism, &c.

It is difficult to predict which, of the spectroscope or of the discovery of some reagent, will play the most important part in the process, but there is here a wide field open to experimenters in the various applications of the spectroscope during the production of the invisible image and also during the after development.

There exist also chemicals which, under the influence of some reagents, undergo a very remarkable change in colour; and some go through a succession of colours which, no doubt, in a more advanced stage of our knowledge, shall be taken advantage of in photography in natural colours. The following is an example of such change: If a small piece of strychnia is dissolved in a drop of strong sulphuric acid on a piece of white porcelain or of glass, and close to it a little finely powdered dioxide (black oxide) of manganese is mixed with a similar quantity of sulphuric acid, then the two brought together, a beautiful play of colours takes place—first a rich purple-blue appears, which gradually changes into crimson and then into reddish pink. The same effect may be produced if bichromate, or permanganate, or ferriyanide of potassium are used instead of the dioxide of manganese. The same result can be obtained also if, instead of the latter reagents, peroxide of lead is used dissolved in strong sulphuric acid mixed with one-fourth of its bulk of strong nitric acid.

In closing this letter, we wish to mention that we have not the least idea of having pointed out the means of arriving at a solution of the intricate problem in question; but our intention is merely to bring our opinion into contact with that of others, in order to improve our knowledge by mutual criticism, which is the rectifying process of all embryonic theories.

The experience of different men, and likewise their knowledge of any art, vary from the different points of view which every individual takes of it. One acquires more experience in the practical part, another in the scientific or theoretical, and each of these in different directions. The union of all such individual experience constitutes the greatest possible knowledge.—We are, yours, &c.,

OFFELEIN & Co.

54, Berners-street, Oxford-street, London, May 23, 1887.

[Our correspondents do not appear to perfectly realise what the nature of Mr. Mayall's "invention" really is. It has nothing whatever to do with the obtaining of photographs in natural colours in the camera, but with a method of applying colours to photographic prints by which they will have a more natural appearance than if they were allowed to remain uncoloured. The only question between the Mayall method of colouring and any others, such as the crystoleum, of which we have published the details, direct and modified, times innumerable, will be which is likely to produce the best effect, and on which side will the balance preponderate. Mr. Mayall or his friends claim that by his method the colours can be applied in a couple of minutes or so; but this may be an error, seeing that a portrait, for which we sat on the 17th instant, has not yet been completed up to the time of our going to press.—EDS.]

PHOTO-MICROGRAPHY.

To the Editors.

GENTLEMEN,—As I am the Fellow of the Royal Microscopical Society alluded to in your last number as having exhibited photo-micrographs which had been obtained by means of a sliding diaphragm, perhaps you will kindly allow me sufficient space to explain more in detail the means by which I obtained them. After three years' experiments in various directions in endeavouring to get satisfactory photographs, I at last came to the conclusion that with the objectives I commonly use, varying from one-and-a-half inch to one-eighth, I got a great deal more light from my paraffine lamp than I could possibly need. Stops in the objectives, besides being contrary to the principles and intentions of the accomplished opticians who made them, introduced so many errors by their proper performance being interfered with that I gave that up; but still I had the difficulty of too much light, the details of my preparations being drowned in the flood of it. I therefore got over this difficulty by adding to the back of my object carrier a tube having a slot in one side and a sliding diaphragm, which I could thus move backwards or forwards till I could bring out and focus the details of my subject, limiting the amount of the light by taking only so much of the cone of rays sufficient for this purpose. Since then my results have been more satisfactory in every way, while the just performance of the objectives was left intact.

I firmly believe the knowledge of this method of operating will be of advantage to those who have recently taken up this most interesting branch of photography.—I am, yours, &c.,

T. CHARTERS WHITE.

32, Belgrave-road, S.W., May 25, 1887.

AN ANSWER TO "FREE LANCE."

To the Editors.

GENTLEMEN,—Your errant correspondent "Free Lance" wants to know what I mean when I say that "sodic sulphite requires careful neutralisation with acid." Well, as usual, I mean what I say—namely, that sodic sulphite, when used as a pyro preservative, requires careful neutralisation with acid. I am not aware that I mentioned or alluded to the action of the soda salt as affecting the development of the plate. If "Free Lance" thinks that the acid is not required, let him add four ounces of sodic sulphite in solution to an ounce of pyro, without the acid, and then let him tell us how the sulphite works as a "preserver" of pyro.

I have to-day added one hundred and sixty grains of sulphite in solution to forty grains of pyro without neutralising the former, and the mixture is already darker in colour than it ought to be after six months. My sulphite is of the best quality, as I believe; it cost the top price and came from a good house.

I never had the pleasure of meeting the late Colonel Russell, whose death you mentioned in your last issue, but his name has long been known to me as one of the most honoured in photography, and I hope it may not be taken for presumption on my part that I venture to express my sincere regret for the death of such a man. His modesty seems to have been as great as his ability.—I am, yours, &c.,

Craigleugh, Langholm, N.B., May 21, 1887.

ANDREW PRINGLE.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—The writers on this subject in your JOURNAL have not confined themselves to the question, "To whom does the portrait negative belong?" What reasons can photographers advance to justify their claim to the ownership of it? No writer yet has advanced one reason to justify that claim. Custom, when questioned, is no reason.

I am sorry to read that Mr. Basbe, of Sheffield, has, after twenty-five years' experience, to confess that he can rarely secure a really good negative a second time. His inability to do this is certainly a fairly good reason for his opposition to the destruction of his good negatives when secured, but is no reason that these negatives should be claimed by him as his. To claim the cake and the halfpenny is morally bad.

Mr. Basbe writes, "I do not use argument—it is not necessary." Permit me to add, it is so unpleasant.

Mr. Basbe seems to have overlooked, when writing, that he was addressing himself to photographers, and not to the general public.

Photographers do, as a rule, know how to conduct their own business, and, as a rule, they endeavour to please the public, from whom they receive their daily bread.

As a photographer since 1851, I again repeat that a photographer has no right to the ownership of a portrait negative, that he has not one reason to advance to justify his claim to it, and, more, that the destruction of the portrait ought to be imperative if requested by a client, and on an unwilling photographer should be enforced by law.

The destruction of the negative would be no loss to the photographer, but in the end would prove to be to him a monetary gain.—I am, yours, &c.,

Newcastle-upon-Tyne, May 23.

J. F.

To the Editors.

GENTLEMEN,—The question of the proprietorship of the portrait negative has been discussed at some length in your JOURNAL, but all your correspondents appear to have missed the point.

The glass and the film is no doubt the property of the photographer, the same as the camera lens and other appliances which enable him to produce the photograph, and custom has given him the right to keep it, but the impression on the film is undoubtedly the property of the sitter, not because he has paid for it, but because the photographer has no right to print and sell copies without his permission. The sitter has also the right to order the destruction of the impression on the film, and no respectable photographer would object to comply with this request, knowing that no more copies would be required after such a request had been made.—I am, yours, &c.,

Bath, May 23, 1887.

J. DUTTON.

To the Editors.

GENTLEMEN,—As my first letter to you on this important subject has called forth several expressions of opinion, it may be interesting to yourselves and to your readers to know how the contention has ended.

I am pleased to tell you that it is in a manner eminently satisfactory to the profession, as my customer has practically admitted the justice of my demand by sending a cheque to my Solicitor for the amount claimed by me as the price of the negatives, namely, one guinea each, with 1s. 6d. for packing and postage.—I am, yours, &c.,

28, Union-street, Ryde, Isle of Wight.

ARTHUR DEBENHAM.

PHOTO-THERMOGRAPHY.

To the Editors.

GENTLEMEN,—In connection with the very interesting article on this subject in your issue of May 13, permit me to call your attention to the following:—"If a sheet of paper on which a key has been laid be exposed for some minutes to the sunshine and then instantaneously

viewed in the dark, the key being removed, a fading spectre of the key will be visible. Let this paper be put aside for many months where nothing can disturb it, and then in darkness be laid on a plate of hot metal, the spectre of the key will again reappear."

I, some time since, extracted the above from a work called *Nature's Secrets*, published by Houlston & Wright, 1863, intending, if time permitted, to verify the statement by experiment; but pressure of business has prevented. I, therefore, send it to you, thinking that some one may like to test the matter who has more leisure than—I am, yours, &c.,

J. MARTIN.

Printing and Enlarging Works, 4, Park-villas, New Southgate, N.

THEATRICAL PHOTOGRAPHS.

To the Editors.

GENTLEMEN,—In reply to Mr. Hyslop's letter in your last week's issue I regret that any remarks of mine should have been construed into a grievance against this Club. I have no grievance whatever against the Club and no wrongs to air. Without troubling you with categorical replies to his questions, I am quite willing to admit that the formula which he gave me at an early stage of my experiments was of material use to me, although the plates I finally used were not prepared by that formula.

What I intended to assert, and do assert still, is that the idea of photographing the theatrical scenes by means of orthochromatic plates was entertained by me and put in the way of being carried out long previous to my acquaintance with Mr. Hyslop, and also that my pictures were actually taken some weeks earlier than his. Thus I in no sense "followed his example." I am prepared to prove this to Mr. Hyslop's satisfaction if he thinks it necessary to dispute it, and to show him certain letters on the subject which are in my possession, but which I do not think it necessary to put into print.

With apologies for troubling you at such length—I am, yours, &c.,

JOHN F. ROBERTS.

Camera Club, 21, Bedford-street, W.C., May 25, 1887.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange limelight jets and pair of five-inch double condensers in brass cell for single view lenses.—Address, C. ROWLAND, 39, Cecil-street, Carlisle.

Will exchange a Dallmeyer lens, 1½ (long), and half-plate view lens, by Mayno, of Dublin, for good half-plate camera with double slides and stand.—Address, J. DAVIDSON, 79, George-street, Edinburgh.

Wanted, half-plate portable camera and lens, slides, and tripod, in exchange for whole-plate burnisher, three volumes of the JOURNAL (1884, 1885, and 1886), ten ALMANACS, and other things.—Address, M. GRANT, 419, Kingsland-road, E.

Will exchange 10x8 portable camera, with one single or one double dark slide, for half-plate or 7x5 camera, with three or more double slides, by good maker; also interior background, good condition, for another ditto.—Address, WHITEHOUSE, Dolgelly, North Wales.

Last six years' BRITISH JOURNAL OF PHOTOGRAPHY, half-plate repeating-back camera, half-plate portrait lens, half-plate view lens by Marion, strong tripod stand, copying camera, 11x9. Wanted, 12x10 view lens and a whole-plate camera.—Address, W. B., 32, Stoke-road, Guildford.

Will exchange mahogany studio camera, eight inches square, with or without half-plate lens, also quarter-plate sliding-body camera, lens, and mahogany tripod, studio stand, and pair of single stereoscopic view lenses, for posing chair, balustrade, or other accessories for studio.—Address, W. HYETT, Photographer, Cheltenham.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

J. White, Salford.—Photographic group of Prince and Princess of Wales at Peel Park, Salford.

J. Edge, Stretford-road, Manchester.—Photographic group of Prince and Princess of Wales at Peel Park, Salford.

Messrs. Powls & May, Birmingham.—Five portraits of Mademoiselle D'Alcourt.

OXON.—There is no photographic directory published.

R. C.—The matter is very simple. Have no further dealings with the firm.

F. B. SYMES.—A microscopic objective for your purpose should be slightly under corrected.

O. B.—1. The person you name is a charlatan and the scheme a swindle.—2. It was in Chicago.

KATHERINE C.—There is no such agency. Your only plan will be to advertise in the foreign photographic journals.

W. C. H.—Bitumen suitable for the purpose may be obtained at any operative chemists or at most drysalters and dealers in varnishes and polishes.

G. B. ROBERTSON.—A five-inch head is quite large enough for the sheet of paper you employed, the assertion of your artist customer notwithstanding.

BOAZ.—The washing apparatus mentioned is very ingenious. If you have a simpler arrangement which answers the same purpose it is of course an improvement.

A. W. S.—1. So far as we are aware, such an apparatus has not been used before or been patented.—2. We think it would be quite worth while to patent your invention.

D. MCP.—A printing bath of a less strength than forty grains to the ounce should not be used for the ordinary run of negatives. For general purposes a stronger one is desirable.

ISO.—We never recommend any particular maker's plates. Orthochromatic plates will answer for general purposes as well as the ordinary ones. Consult our advertisement columns.

TOMPO.—Stop out all the figures not required in the copy with Chinese white, then wash it off when the negative is taken. The bath need not be moved during the time the paper is being floated.

C. L.—1. In keeping a stock solution of chloride of gold, it is better not to add anything at all to the water if the chloride be acid; if not, a drop or two of hydrochloric acid should be added.—2. The quantity of bromide added at a time will depend upon the extent of the over exposure. If the plate be very much over exposed the bromide may be used much more liberally than if only slightly so.—3. It is simply a question of actinism.

W. R. WILCOCKSON asks: "Will you kindly give me a formula for a reducer for over-developed negatives, not chloride of lime?"—One of the best methods of reducing over-dense negatives is to immerse them in a solution of hyposulphite of soda—one ounce to the pint of water—to which a few drops of a solution of the red prussiate of potash have been added. The actual strength of the solution is not very material, but the weaker it is the more of course it is under control.

PERPLEXED.—So far as we can judge, the spots do not arise from the paper but from something in the sensitising or drying. In the example sent the spots appear to be due to some minute particles of reducing matter coming in contact with the paper as it dries. Floating particles of pyrogallie acid in the atmosphere would produce a similar effect. We advise you to discard blotting-paper altogether, and, instead of drying by means of a Bunsen burner, dry the paper before the fire or allow it to dry spontaneously.

W. B. CASSINGHAM asks: "Is it necessary to thoroughly wash a negative before putting it into the alum bath from the hypo? I have seen some operators take the negative from the fixing bath, hold it under a rose jet for about thirty seconds, then place it into the alum. Is this washing sufficient, or does it require a thorough wash? By answering the above in your 'Answers to Correspondents' column you will greatly oblige."—The washing alluded to is far too short. When a negative contains hyposulphite and it is immersed in a solution of alum, a decomposition is set up with a liberation of sulphur and sulphurous acid, neither of which are likely to conduce to permanency.

W. H. STEWART writes: "I have a Daguerreotype to photograph, cabinet size; it is not spoilt, but is brighter in some parts than others, and rather hard to place in such a position as to get the positive view of the image. Could you please inform me how such a picture is to be photographed? I wish, if possible, to take it by the gelatino-bromide process."—If the Daguerreotype is not tarnished it becomes simply a matter of illumination. The picture should be arranged in the position before the camera in which it can be most distinctly seen; then all reflections must be stopped off and the light so arranged that it comes principally from one source. In arranging the Daguerreotype it should be placed so that the light falls in the contrary direction as the plate was polished. By this means the faint lines or minute scratches will be reduced to a minimum. It is impossible to give more definite instructions, as so much depends upon circumstances.

RECEIVED.—*Amateurs' First Handbook*. By J. H. T. Ellerbeck.

We are reluctantly compelled to hold over some Reviews, Notices, Articles, and Correspondence.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Outdoor meeting on Monday, the 30th instant, at Chiddingstone. Train from London Bridge to Penshurst Station at thirty-five minutes past nine.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, June 1, 1887, will be *Retouching and Double Printing*. The Bank Holiday outing at Leatherhead, leaving by the forty-three minutes past ten train from Victoria, and the thirty-five minutes past ten train from London Bridge.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Excursions.—May 28. To Richmond. Members will meet in the booking office at Richmond Station at fifteen minutes past three p.m.—May 30. To Chiddingstone. The train leaves London Bridge (South Eastern Railway) at thirty-five minutes past nine a.m. Book to Penshurst.

CAMERA CLUB.—Thursday, June 9, at nine p.m., Mr. T. M. Brownrigg will give an exhibition of lantern slides made from negatives taken during his recent travels on the Continent. The illustrations will include landscape, interiors, and statuary. The next Club excursions for members and friends are on Saturday, June 4, to Brasted and Westerham; and on Saturday, June 25, to Marlow and neighbouring points upon the Thames.

CONTINENTAL PHOTOGRAPHY..... 330	

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1413. VOL. XXXIV.—JUNE 3, 1887.

HINTS ON THE USE OF COAL GAS.

WE are often surprised to note the slight extent to which the powers of coal gas are utilised in the work of the photographer, and the answers we have received to our inquiries as to the cause of this neglect to render available the capabilities of a most useful servant, have suggested the thought that a few hints on the matter may be of real service. Happily there are, nowadays, in the ranks of photographers many men who have nothing to learn as to the use of laboratory appliances, but they form only a minority among a large body of intelligent workers, comprising many who are possessed of taste and culture, but who have had little technical training of even an elementary description, and to such will our remarks be more particularly applicable.

The letters which periodically appear in the London dailies as to the rapacity, not to say chicanery, of the gas companies, and which a couple of years ago created, by their number and violence, quite a fever among gas consumers, attest the ignorance of the average Briton upon this most simple matter of taking the reading of a gas meter. And it is this ignorance as to how to ascertain the consumption of gas in a given time which gives point to the main objection we have heard alleged against the use of a gas burner for heating or boiling purposes. "They are so expensive," we are told; nothing the makers state as to the maximum consumption has any effect, and the statement is recklessly proffered that all burners "waste such a quantity of gas." As a matter of fact, there are many heating burners obtainable which would not burn threepennyworth of gas if they were employed for twelve hours at a time without cessation in their action. The reading of a meter is most simple. Usually, three faces like those of a watch are visible on the front of the meter; the figures running, unlike those of a watch, from 1 to 10, and also, it will be observed, counting alternately from right to left and left to right. Observing the figures the finger or pointer has last left, these figures are put down, one after another, that on the left face being first; then two ciphers are added. The next time the meter is "read" this process is again gone through. The first lot of figures subtracted from the last tells the actual number of feet used; the rest needs no explanation. It may be observed that no smaller quantities than hundreds of feet are thus given; but it will be quite easy to mentally divide the spaces between the figures on the last face into five parts, and so estimate the quantity down to twenties of feet.

Perhaps, however, the main objection we have heard proffered has, after all, been that gas burners for boiling produce such a disagreeable smelling and vitiated atmosphere that the establishment is best without them. To a certain extent

these objections are well founded, but to a certain extent only. Let us first of all point out to our readers that the ordinary thin rubber tubing fitted with helical wire lining that is usually employed should be entirely discarded, for it is quite pervious to coal gas, and as long as it is in use, and, indeed, for a long time afterwards, emits a most nauseous odour. The tube to be employed for connecting the portable burner to the gas pipes should at the least be of the "extra thick" rubber tube now so commonly sold; it allows very little gas to pass through, even when continuously employed. There is, however, a kind of tube made and sold by Mr. Fletcher which is absolutely impervious to gas, and wherever the smell of gas is a great drawback it should be employed; it can only be obtained in short lengths, but where required these may be joined by pieces of glass tubing. There is, however, a little thought of source of escape which is yet perhaps the most fruitful of all—it consists in the presence of a certain amount of unburnt gas left in the tube after turning off the supply; this portion of gas gradually escapes and pollutes the atmosphere. A chemist of our acquaintance always disconnects the rubber, and applying a light to the burners blows through the pipe. The breath carries forward the unused gas, which then gets burnt and thus no escape is produced. We have recently seen a most ingenious mode of getting rid of this surplus gas. Instead of the rubber being fitted on a plain brass nozzle it is attached to the lower arm of a T-piece (the arms being placed vertically) which takes the place of the nozzle; the upper part of the T is fitted with a tap and an ordinary fishtail or other gas burner, which is usually kept closed. When it is desired to put away the burner after use this subsidiary tap is turned and the burner lighted while the heating burner is still alight. The tap nearest the main is then turned off; the gas ceases to burn at heating burner, but a small light will be seen at the illuminating (upper) burner and will continue until all the gas in the tube has, by reason of its lower specific gravity, escaped through the upper burner. We can commend this as a most useful and practical suggestion.

Then, again, there is—still referring to alleged objections—the cost of employing a fitter to adapt some arrangement for attaching a burner. Now this really need be no difficulty. Mr. Fletcher clearly explains in his various lists a method of attaching a simple little tap for the purpose, a method that a child almost might use. He even makes still another form of tap, which is attached to any ordinary gas bracket. The arm of the bracket is unscrewed, the new tap is screwed on to the female screw of the existing bracket connection, and then the arm is again screwed on. We have then a simple arrangement always at hand without calling in any plumber, and which can be used or not as occasion may require.

There is still the observation to make, that valuable as are the mixed air and gas smokeless burners now to be found in almost every house in the country where gas is used, it is to be remembered that the admixture of air with the gas is only for the purpose of preventing smoke when a vessel of any sort is placed with a gas flame playing over it, for contrary to the usual opinion, the heat from a certain amount of gas is just the same whether it is burnt under ordinary conditions at the familiar illuminating fishtail or other burner, or is first mixed with air before burning. As a matter of fact the illuminating burner when used as a boiling burner would nearly always give a coating of soot to the vessels, owing to the combustion being rendered imperfect through the incomplete and inefficient supply of air to the outer parts of the flame.

Where it is desired to carry the gas some distance from the nozzle to which the indiarubber tubing is attached, economy may be studied by using long glass tubes, joined by short lengths of rubber, the glass being far lower priced length for length than the rubber.

We have said nothing about the furnaces, reverberating or otherwise, for reduction of residues, enamel making, &c. These at some future time may be treated in an article by themselves. Suffice it to say that we have now shown the usefulness and economy of easily available gas appliances, and have shown also how the unpleasant odour so much objected to may be avoided without difficulty.

SMALL ENLARGEMENTS *VERSUS* DIRECT NEGATIVES.

EVER since the first introduction of photography with negatives the subject of the production of large pictures from small originals has been one which has furnished a prolific source of discussion, and, from the attention it has always received, it might, possibly, have been considered as settled. Evidently this is not the case, seeing that it is still of sufficient importance to have formed the topic for discussion at the last ordinary meeting of so important a body as the Photographic Society of Great Britain.

The discussion, in this instance, was not so much as to the best plan of producing pictures of large size, but those of only modest dimensions—twelve inches by nine being specially mentioned. In passing it may be mentioned that these proportions are far better for landscapes than the long recognised ones of twelve by ten. If a professional photographer has to execute work of this size he would, there is little doubt, take the pictures direct. But any one who has had experience in the field with a twelve by ten—or nine—outfit is fully aware that it is a "pleasure" not to be indulged in often without an assistant, unless the artist be endowed with extraordinary *physique* and exceptional powers of endurance. It is for this reason that so few amateurs affect direct pictures of this size.

As the subject was first introduced at the meeting referred to, it was somewhat ambiguous, but it soon resolved itself into the question as to the best method for the amateur to produce, from his favourite seven and a half by five plates, pictures not less than that mentioned, and various plans were suggested. Usually, in discussions of this character, it has been assumed that the original negative is much smaller than that indicated on this occasion, and this somewhat modifies the conditions so far as the ultimate result is concerned. In most former discussions, when this subject has been under consideration

from an amateur's point of view, negatives of about the quarter-plate size, or such as those taken with the so-called pocket or detective cameras, have been alluded to, but in this instance those of double that size were in question.

An enlargement to twelve inches by nine from a negative seven and a half by five is an amplification of a trifle over one and a half diameters, whereas one from a quarter-plate means three diameters—a very wide difference. Of course, with the latter degree of amplification, all spots or defects are magnified three times, but in other cases they are but half this. Again, any lack of sharpness in the original is rendered doubly as conspicuous in the one case as it is in the other. But this is not all, as we shall presently show; for even when the amount of enlargement is the same, the size of the original negative is still an important factor in the case. The enlargement from a quarter-plate to a half-plate is about equivalent to one from a negative seven and a half by five to twelve by nine—namely, one and a half diameters. But all things being equal, the larger picture will possess a far more satisfactory appearance. In the first place the smaller size picture will always be looked at from a much nearer point of view, and will, therefore, be more closely criticised than the larger, so that minor imperfections will become the more conspicuous. The finer details, in most instances, will appear much coarser in the small picture than in the larger one. This arises from the granularity of the image, owing to the particles of the bromide of silver being too coarse in themselves to render the finest details in their true proportion.

If we consider for a moment how exceedingly minute some of the lines and points seen in nature are—say the hairs in a man's beard for example—we can form some conception of how extremely fine and delicate they must be in the negative for them to be in correct proportion. All know how very large the particles of bromide of silver are in some dry plates, particularly in those of the most sensitive kind. Now it is clear that the coarser the particles are, and the smaller the image is, the less correctly will the finest details be rendered. The atoms of bromide of silver in the film of a seven and a half by five plate are, of course, the same size as they are in that of a quarter-plate, but the size of the image on the former will be nearly double. Consequently, if the molecules of bromide be too coarse to render the finest details correctly, or in their true proportion, in the smaller image, they need not, necessarily, be so in the larger; and, even if they should be, then the error will be reduced to one-half in the larger negative of what it is in the small one. And, as a consequence, when the two negatives are enlarged the same number of times, whatever they may be, the result from the larger one will be the more satisfactory of the two.

Much of the "woolliness" often seen in portraits which are enlarged from small negatives is due to the molecules of reduced silver, in the original, not being sufficiently fine to render the most delicate portions of the picture correctly. Although this woolliness is more conspicuously seen in the enlargement of a portrait it nevertheless exists just to the same extent in one of a landscape, though it is not so distinctly recognised as such. From this it will be seen that when small negatives are taken with a view to their subsequent enlargement and the best results are desired, the plates should be prepared with an emulsion in which the bromide of silver exists in the finest possible state of division, even if this quality entails the sacrifice of a certain amount of rapidity.

In the foregoing we have pointed out some of the reasons

why better enlargements can be made from negatives of moderate size than from the small ones, so frequently advocated for amateur purposes.

APPROPRIATE of our article in last week's issue describing a method of vignetting by a mask of thin sheet lead, we have received from Messrs. George Mason & Co., Glasgow, a sample of metallic vignetting masks which have for some time been manufactured and sold by this firm. While those of Messrs. Mason & Co. are highly effective, they differ from Mr. Lyonel Clark's to this extent, that they are composed of thin zinc, with serrated edges to the aperture, which also turns back all round, while the speciality of Mr. Clark's lies in their being formed of very pliant lead, which are retained in position by being lapped over the sides of the frame.

Do dry plates keep so well now as they used to do? This is a question put the other day. Some time after gelatine plates became general it was assumed by many that they would keep almost indefinitely, and cases were quoted where they had remained good for a considerable period and under decidedly adverse conditions. Experience has, however, proved that several brands of commercial plates very quickly deteriorate, and show the well known iridescence round the margin when the negative is developed. This defect is usually attributed to sulphuration, but how produced is very much a matter of opinion, as all the theories hitherto promulgated are open to question. May not the gelatine itself, in some instances, be an important factor in the case? Many of the finer kinds of foreign gelatine sold in thin sheets—such as those used by some dry plate makers—owe their whiteness to their being bleached with sulphurous acid. Some samples of these gelatines that we have met with in commerce have possessed a very strong and unmistakable odour of burning sulphur. Such gelatines, it is scarcely necessary to say, are certainly undesirable to employ in the manufacture of dry plates; yet we have seen them used and excellent plates result, but we had no opportunity of judging of their keeping properties. Keeping qualities in dry plates are important, and are well worthy of consideration with manufacturers, although this is a subject which appears to receive but little attention at present.

A NUMBER of letters have appeared in our daily contemporaries on the subject of Mr. Mayall's method of colouring photographs. Some of the letters have been amusing enough if only on account of their ambiguousness. Evidently some of the correspondents have assumed, like the writers of the leading articles on the subject, that the pictures (?) are actually produced photographically in the natural colours instead of being coloured by hand. But Mr. Mayall has made no such claim, nor could he do so. In the matter of coloured photographs there are "two Richmonds in the field." There is another scheme really claiming to produce "photography in natural colours" being exploited just now. Of this second venture we may have something to say next week.

In the Science Department at South Kensington are some examples of early photography which are interesting as regards permanency. They are transparencies on glass by the collodion process enlarged from small negatives of the moon and the eclipse of the sun of July 18, 1860, taken by Mr. Warren De la Rue. Some of them appear to be unaltered, while others have become much discoloured. We are unaware whether they were toned or not, but some look very much as if they had been treated with mercury. In most cases where they have become discoloured, the discolouration appears to have been caused from moisture being imprisoned between the glasses and acting on the image. This interesting collection at the present time looks in a very neglected condition, and as if the pictures, probably, would not have changed to the same extent had greater care been bestowed upon them. This is to be regretted, as very early photographs by the different processes are now becoming rare, and they will always be valuable for reference, particularly when permanency is in question.

A SHORT time back we commented on the faded condition of many out of a series of portraits in the Patent Museum, and the desirability of having them copied before the deterioration proceeded further. Faded and fading photographs are not confined to the Patent Museum alone, as they pervade the different departments at South Kensington generally. This is somewhat to be wondered at, seeing that some well-known photographers are connected with the establishment. At the time some of the photographs were produced there was no really permanent method of printing known. But now there is no reason why these pictures should not be copied and printed by a permanent process—carbon or platinotype, for example. Intaglio plates by the etching process are now produced commercially at a low rate, and it would not be costly to have the photographs reproduced by this means. In this case the image would be in printing ink, and the plates might be retained for the production of impressions whenever required for other museums or exhibitions. Surely if the photographs are of sufficient interest to have a place in any of the departments, they are valuable enough to be properly maintained instead of being, as they are, little better than a reproach to photography. So much money is annually granted for the South Kensington establishments that a little extra for so useful a purpose ought certainly not be begrudged.

AMONGST the photographs in the different departments at South Kensington, those shown in the Indian section seem, on the whole, to show the greatest signs of stability of any of the silver prints. Whether this is in any way due to the vigorous character of the negatives from which they were printed or not, it is of course impossible to say, but there is ample evidence in the prints that they were made from much stronger negatives than are in vogue at the present time. The character of the light in India is such that it conduces to vigour in the negative, especially when the wet collodion process was employed.

ON THE PRESERVATION OF FERROUS SULPHATE IN SOLUTION.

ONE of the chief drawbacks to the use of the ferrous-oxalate developer is the difficulty of keeping it in its best and most active condition. This difficulty has only been removed a stage further back since the introduction of the method of preparing it by separate solutions of ferrous sulphate and oxalate of potash mixed when required for use, the ferrous sulphate being as prone to change as the mixture of the two solutions. In THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the present year, two or three suggestive articles may be found bearing on this subject.

One recommends keeping the solution of ferrous sulphate saturated with carbonic acid gas. This, however, is not easy unless the arrangement adopted allows the gas to be accumulated under pressure as in a gazogene, as otherwise it is difficult to extract the solution for use without admitting atmospheric air, which quickly leads to oxidation, besides which there is some uncertainty and trouble as to obtaining the ferrous sulphate itself in a state of pristine purity. If this is attempted by washing the crystals, it is uncertain where to stop, and impossible to weigh the wet crystals, and even if weighed in solution by the specific gravity method there is complexity and room for error.

A more excellent way is therefore desirable, and this is found to perfection by resorting to a method used by analytical chemists for reducing the persalts of iron to the protosalts, and that is by the introduction into the solution of ferrous sulphate of small fragments of metallic zinc along with some acid—citric acid will suffice. For the purpose in view, commercial sheet zinc answers perfectly well, and its impurities have the advantage of setting up that galvanic action which is necessary for its rapid action. The analyst, who requires to use the pure metal, has to employ platinum to set up this action.

Any one who tries the experiment of inserting a few strips of zinc into a yellow solution of iron salt will be charmed with the rapidity and perfection of the result obtained after standing a few hours. Hydrogen gas is liberated and must be allowed to escape if an ordinary bottle is used, or it may burst.

The writer by this means most effectually deoxidised a very yellow

and foul looking solution obtained by dissolving a pound of green vitriol. Paraffine oil, to the depth of three-quarters of an inch, was placed also in the bottle, through which the gas escaped. The solution is now a brilliant green. To remove it for use readily, a syphon is formed of glass tube bent into an inverted U shape; one leg is passed through a cork in the neck of the bottle, the other is supplemented by a piece of indiarubber tube provided with a clip; another short tube passes through the cork and is lightly covered (not closed) with a cap of indiarubber tube to provide for the admission of air whilst excluding dust. The syphon being once started, stands full; when not in use the clip with the indiarubber being raised is supported between the glass tube and the bottle, and this allows of the bottle being removed to a shelf or table without risk of breaking the syphon.

Some solution of ferrous sulphate prepared with carbonic acid gas, which had become a little yellow through accidental introduction of air, was quickly revived by the introduction of a minute fragment of zinc.

The quantity of zinc used up in deoxidising the solution of green vitriol was hardly more than one inch square of sheet zinc. More was placed in, but when the action was found to be complete the solution, including the paraffine oil, was decanted into another bottle without any trouble.

The adoption of this simple process enables one to be always supplied with the means for ferrous oxalate development, and thus one of the drawbacks to its use at once vanishes.

Prepared with ingredients thus purified the developer will be found exceedingly powerful, and of great value where stripping films are in use or where negatives are being prepared for enlargement, as the great translucency of negatives developed by ferrous oxalate saves much time during the process of enlargement, and as to the stripping films, allows of the stripping process to be deferred to any length of time with the certainty of success. The property which metallic zinc has of reducing persalts of iron to protosalts suggests the possibility of employing it for keeping in active condition a ready mixed solution of ferrous oxalate or even of restoring with promptitude and efficiency the solution, after it has been already used for development. In chemistry, above all, it is never safe to prophesy unless you know, and until trial is made one cannot be sure; but should this suggestion prove feasible an immense economy will be effected in saving the large amount of oxalate of potash hitherto wasted.

Metallic iron used to be employed for the purpose under consideration, and it may be that its inefficiency was owing to the absence of any provision for the second metal necessary to set up galvanic action, the metallic iron employed being far purer than ordinary zinc.

In using zinc to reduce ferric oxalate to ferrous oxalate as in the used developer, there will not be that easily observed change in colour which helps so materially one's proceedings in the case of ferrous sulphate. But if the solution of ferrous oxalate be kept in a gazogene such as used for home-made soda water, the hydrogen generated by the zinc can be made to ensure the absence of air and suffice to expel the liquid on pressing the tap. If necessary, this may be supplemented by introducing a few crystals of bicarbonate of potash and citric acid.

G. A. KENYON, M.B.

P.S.—Since writing the foregoing I have utilised that modification of the gazogene used for retailing soda water under the name of "Syphon." One of these is obtainable for a couple of shillings at any chemist's. Half a pound of sulphate of iron dissolved in thirty-two ounces of water was introduced, then some strips of zinc about three-quarters of a square inch, then 120 grains of bicarbonate of potash and 150 grains of citric acid, both in crystals. The screw-top was then leisurely alixed. This gives a solution half the strength of the Eastman formula, so reduced to facilitate measuring, with the required amount of free acid.

PAPER NEGATIVES IN ORDINARY SLIDES.*

BUT the gumming business still exercised my mind, and the trouble of cutting off the exposure and removing the fragments from the carrier; but a better method would not suggest itself until one day I saw a clerk "graphing" some circulars on one of the slabs of moist gelatine used for the purposes of cheap reproduction. Here was the very thing I wanted; something that will stick, not too much, but just enough. The only question was, How long will it retain its adhesive power and still exhibit the obliging readiness to part company with its prisoner? I may say that I have satisfied myself on that score over a period of several weeks, pieces of paper which have been adherent to the ferrotype plate during that time coming away with the greatest ease.

The gelatine mixture I make as follows:—

Gelatine (or fine glue)	1 ounce.
Golden syrup	$\frac{1}{2}$ to 1 "
Glycerine	4 ounces.
Water	7 "

Soak the gelatine until thoroughly swelled in the water, and, having liquefied by heat, stir in and thoroughly incorporate the glycerine and molasses. The latter gives a stickiness and "grip," which, with some samples of gelatine, especially of the "hard" class, the glycerine seems to partly counteract. The softer non-alkalised gelatines answer best, or a good sample of glue may be used.

And now for the method of using this. I need hardly say that the prospect of leaving a sensitive gelatino-bromide paper film in contact with a moist surface, such as that the mixture gives, for perhaps a week or two, did not strike me as very promising, so I departed from the "chromograph" method of bringing the whole surface of the paper into contact with the gelatine, and contented myself with causing it to adhere only at the edges. The following is the plan I adopt. The melted gelatine is poured out into a flat, shallow dish (the lid of a tin biscuit box answers well) to the depth of an eighth of an inch, and this is placed on a stove to keep it liquid. The metal carriers are then dipped into this, each edge successively being allowed to set before the plate is turned so as to prevent the gelatine "running." In this manner a neat, clean edging of the adhesive is quickly applied, and the carriers are then reared up on a clean place until wanted for use.

To apply the films, upon a sheet of clean paper lay one of them sensitive side downwards, upon this accurately superpose the carrier, and upon that again another negative paper, this time sensitive side uppermost, covering the whole with another sheet of clean paper, and passing a squeegee three or four times over the whole. The two films will then be found in perfect adhesion. If the carriers have been "edged" some time and become surface dry, instead of the squeegee a warm iron may be used to smooth down the papers; this, by slightly melting the gelatine, will cause adhesion.

To remove the films after exposure, it is only necessary to insert the point of a penknife between the papers and its support and to gently separate them, pulling at the raised corner, taking care not to tear the paper. If they will not part—a contingency that has not arisen with me—the whole, carrier and films, may be soaked in water until the gelatine has sufficiently softened; they will then be easily removed for development.

By adopting this plan any one who is the possessor of, say, a $7\frac{1}{2} \times 5$ camera and three double backs, may at a cost of about seven or eight shillings for a dozen ferrotype plates, 14×10 , equip himself to start on a tour with six dozen sensitive films and with nothing in the shape of photographic impedimenta to carry beyond his ordinary camera case and stand.

C. BECKETT LLOYD.

NOTES ON SOME AMERICAN STUDIOS.

AMERICAN portraiture is so well known in England, or, for the matter of that, I suppose, all the world over, that a few words on a couple of New York studios or "galleries" which I recently had the pleasure of visiting may not be uninteresting to English readers. It was through the kindness of the editor of the *Photographic Times* that I had the opportunity of visiting these, of which kindness, were it not a purely personal matter, I should like to say much.

* Concluded from page 325.

The name of Mora is so well known in Britain that it was with pleasure I hailed the opportunity of calling on the great man. Mora is a much younger man than I expected to see, considering that I was familiar with his work, even north of the Tweed, I think quite fifteen years ago. He has not the appearance of being over forty. He received me with great cordiality, and was kind enough to let me see the whole of his establishment, which is of quite historic interest, having been the first Daguerreotype gallery in America. It was opened in the year 1841 by J. Gurney, who did a very large business in Daguerreotypes from that time till the glass positive superseded the older form of sun painting. The magnitude of his operations may be imagined from the fact that he was in the habit of turning out portraits as large as 17 x 11 inches, and that he found it worth his while to have a steam engine to work the wheels on which he polished the plates. These particulars I had from Mr. Gurney himself, whom I afterwards had the pleasure of meeting.

As might be imagined, a studio which has been in use for over forty-five years has little of the varnish of newness about it. Indeed, Mora appears to be by no means desirous of show. The gallery is, I imagine, not very different from what it had originally been, and one was impressed with the generally unassuming appearance of a place so well known. The studio itself is sufficiently large, without being by any means colossal. It faces, I think, to the north, and, whilst I was in it, at any rate, work was carried on with a great deal of light, one reflector only being used to light up the shadow side of the face. This is divided horizontally, each half being on hinges, so that it can be caused to take any of the following forms, or various others, ac-

cording as it may be desired to cast the light upwards or downwards, or horizontally.

Mora's method of posing is quite different from that of any other photographer I have seen working. He studies the face for a few moments, first one side and then the other, and appears at once to make a mental note of what sort of picture he will make. He places a chair in position, and immediately that the sitter is in it, goes right up to him and adjusts his head, &c., not appearing to need to look what the effect will be from the camera, but knowing by instinct—or rather, I suppose, it really is by great skill and long practice—what the effect seen from the camera will be. He adjusts the reflector, fixes a mark for the sitter to look at, and leaves all the rest to his operator.

Mora still prefers to use wet plates rather than dry whenever he can, wherein I believe he stands alone amongst New York photographers. I could not get him to give me a very definite answer as to why he prefers it. He would not commit himself to any opinion that he got better results, and, indeed, beyond saying that he could with a wet plate see at once what his result was, he would give no reason.

I had the honour of sitting to Mora. He made in all six exposures—or, to speak more strictly, he posed me for six exposures—two on each of his wet plates, and two on a dry plate. I noted that the exposures on the wet plates were from twenty to thirty seconds, whilst those on the dry plate were only about three seconds. With the wet plate, the lens—a Dallmeyer portrait lens, 3½, I think—was used nearly full aperture; with the dry plate, a stop about one-third the diameter of that used with the wet plate was inserted. Now it follows, from this, that whatever may be the average ratio of the rapidity of wet and dry plates, the particular dry plate used on this occasion was at least eighty times as sensitive as the particular wet plate.

I saw all the plates developed, the wet plates in the usual way coming up very rapidly, and requiring no intensification or redevelopment. The dry plate developed with a slowness and caution very different from what is customary in the dark rooms of studios in England. I think quite twenty minutes were occupied in bringing it up; but I was told that, as a rule, development went on more rapidly. Undoubtedly, the result was a negative of magnificent quality.

I may mention that Mora—or, rather, his assistant, because, as I have said, Mora himself confines his attention to posing merely—works dry plates by artificial light filtered through “Debenham’s” medium, in which he strongly believes.

It is well known that American photographers do much more work than English in large portraits taken direct, and Mora is no exception to the rule. I saw huge piles of negatives from which prints might be made on whole sheets of paper. Of course, for these dry plates are used, and little seems to be thought of negatives about 24 x 18 inches in size.

I saw, at the Scovill Manufacturing Company, a camera which had been made for some enterprising individual who intended to go in for direct portraits on plates 34 x 24—a goodly size, surely. Enlarging appears to be comparatively unpopular with American photographers, and certainly the impression made on me by the large direct portraits that I have recently seen is, that there is something in them which enlarging will not give.

The price that Mora charges is, I understand, fourteen dollars (say £2 18s.) for a dozen cabinets; ten dollars (say £2 2s.) for half dozen; and I imagine that he has no difficulty in getting the price.

The next studio that I saw was one of a very different character from that just described. It is the gallery of C. D. Fredericks. This is an establishment for turning out large quantities of work at comparatively low prices. Not that there was anything of the “cheap and nasty” about the work sent out by Fredericks; on the contrary, it would rank in England as excellent portraiture. The general aspect of this place is the very opposite to that of Mora’s. Here everything is magnificent to a degree. The reception room, which occupies the whole of the ground floor is really quite a picture gallery, and is a place where an hour or so might very comfortably be spent.

Again, I was allowed to see whatever I wished through the whole establishment. Upstairs there are two studios where dry plates only are used, and where, at times, Fredericks told me as many as 250 sittings a day are got through. The printing part of the establishment is on the roof, and it is not unusual, I was told, to turn out as many as 1500 prints in a day, the smallest size being cabinets, for I should mention that the *carte* appears to have entirely disappeared in America, or in New York, at any rate. The prices charged are five dollars (say £1 1s.) per dozen cabinets, but I understand that a great deal of “club” business is done. In this a certain number—I think a minimum of six—form a club, and get a very substantial reduction in prices; in fact, from five dollars to three, the latter price (12s. 6d.) being one which would be considered very low for even tolerable work in England.

In both the establishments that I have been writing of I saw the printing department, concerning which let me first of all say, that the light in New York is of such a character that it is not necessary, as it is generally considered to be in London, to have a separate printing establishment at some distance out of town. Each photographer does his own printing at the top part of his own house.

The favourite albumenised paper in both Mora’s and Fredericks’s house is of German manufacture, evidently, by the smell of it, from the same source as a very favourite brand of paper in England. The paper after sensitising is hung up by American clips at two corners, right over a row of Bunsen burners, the heat of which serves to dry it, the products of combustion of which appear to be in no way feared. When dry the paper goes to the fuming box, which is simply a rectangular box or cupboard in which the paper may be hung vertically, and on the bottom of which may rest a dish of liquid ammonia.

Fuming is, as is well known, universal, and all but universal in America, and I must say that the impression produced on me by the results I saw was that it is wise to use it. Taken all round, there was a greater richness in the prints than I have been accustomed to see at home, and this certainly not due to the paper used—for that in the instances I have been referring to was of a well-known European brand—but due, I feel sure, to the fuming, and to that only. A deep purple or almost black tone is the one most affected. I saw little or nothing of the warm browns now so popular in England.

A few very good platinotype prints of large size and excellent quality I saw; but this printing process appears not by any means to have reached the popularity that it has “on the other side,” nor has the gelatino-bromide process—but this latter follows naturally from the fact already stated, that enlarging is much less made use of.

Gelatine dry plates—both bromide and chloride, I believe—are specially prepared for lantern slide and general positive purposes, but, so far as I have seen, only the black tone is affected. I do not know whether because, as in the case of prints on albumenised paper, the brown and reddish colours are not cared for, or because difficulty is found in getting these colours.

On the whole I think the Americans well sustain their reputation for supremacy in the matter of portrait work, certainly at any rate where large sizes are concerned.

W. K. BURTON.

ODDS-AND-ENDS.*

A MEMORANDUM now as to development, but one I would not venture to state as a "fact." Most photographers are, I think, in the habit of finishing off development, when sufficient density is all but obtained, by adding another drop or two of alkali, in order to get "pluck," as it is called. My impression is that this finishing touch is best given by a different alkali from the one that development has been carried on with, thus—an ammonia developed plate I would finish off with carbonate of soda or potash, and soda I would finish with ammonia. This may be a superstition, but for a long time I have fancied the plan to produce the best printing negatives.

I have sometimes, when a plate has been half developed with ammonia, washed it under the tap and finished in a new solution of pyro and potash, or soda. Indeed, so that you keep development in hand, that is, do not let it go on too fast, it seems to me you may play as many pranks as you like without running any great risk of ruining your negative. When Mr. Wollaston, who gave us the demonstration last session of the Eastman paper process, explained his developer, those of you who heard him will remember that he, too, though advising the use of the soda developer, recommended ammonia as a finisher.

Intensification.—The common plan is first bichloride of mercury, then, after washing well, weak ammonia—but I find sulphite of soda much pleasanter than the latter. First soak the negative for a few minutes (though this is not absolutely necessary) in water. Put into saturated solution of bichloride for a very short time till it just begins to bleach, wash for a second or two (that is an important saving in time), then put in a bath.

Saturated solution sulphite of soda 1 drachm (fresh mixed).

Water 2 ounces.

The negative quickly darkens, but will not *over* do itself, and when finished is of fine steel blue colour, like a ferrous oxalate negative, the clear glass not being in the least clouded. If still too thin, repeat the whole process, as often as you like. I have done it three times, and finished with a negative that no one would suspect to be an intensified one.

One unfavourable day in the spring, having obtained permission, I visited Belle Vue Gardens and met with many failures. One portrait that I attempted to take was that of the polar bear, an animal always in distressingly active perambulation. I got a shot at him as he was passing along the nearest part of his circular racing path, and on coming to develop could get nothing at all out of it. Still I carried it to the end, but when the hypo had cleared it, I found nothing but red fog and the very faintest trace of an image, which no one in the world would have supposed to be a bear. I put it aside, and next morning intending to wash the film off put it under a tap of very hot water, and was surprised to find that the image became very much clearer, so before the film gave way I stopped the hot washing and put it away again. When it was dry red fog still enveloped it, so I put it in bichloride of mercury, which, of course, only had the effect of whitening it; then in sulphite of soda, which almost cleared the fog away, leaving a negative which if neither useful nor ornamental was still in great contrast with the original state, and a great advance upon it. Query: If under exposed plates, after being protected by alum, were plunged into hot water for a second or so, would development be affected?

It is sometimes a little difficult, even with such injunctions as Mr. Brunel's in one's memory to distinguish a fact. Here is an instance:—

On coming to develop the plates I exposed in Norway, I was much troubled by frilling, though I had never met with it before to any serious extent in the plates I was using (Fry's). My friend Mr. McKellen advised me to use a solution of Epsom salts before commencing development and I adopted that course. I also used sulphite of soda in the developer, which I do not commonly use, and for the purpose purchased a new bottle, with a well-known name upon it. I must now quote from my notes made at the time.

Plate 1. Put plate for five minutes in solution (ready saturated) of Epsom salts. Washed well under tap. Put it in pyro solution, two grains to ounce, with half drachm saturated solution sulphite of soda, just made up. Left plate in this for five minutes, and on uncovering it was surprised to find it almost fully developed, but appearing rather over exposed. Washed it under tap and placed it in a weak

* Concluded from page 330.

bromide solution; finished development by putting it back into the pyro.

Plate 2. Same treatment, but Epsom salts much diluted. Result same.

Plate 3. Added half drachm ten per cent solution of washing soda to the pyro. Result: film frilled completely off.

Altogether I developed five plates, varying the proportions of the developer, and with the exception of the one mentioned with which I used soda, all developed out without an alkali.

How was this to be explained? I had the Epsom salts analysed and found pure. I blew up Mr. McKellen for recommending such stuff, but this did not explain where the alkali came from. Then I suspected, as I ought to have done before, the sodium sulphite, had it analysed, and the "fact" was made clear; it was strongly alkaline, and it, in combination with the pyro, had developed the plates.

I feel that I have given quite sufficient odds-and-ends for one evening, but as paper negatives are occupying a good deal of attention at present, will give a developing formula of a friend who formerly resided in Manchester, Mr. T. G. Waite, now of Edinburgh. He advises pyro and ammonia instead of pyro and soda, and gives the following formula:—

A.

Pyro, made up with sulphite of soda of the usual strength.

B.

Ammonia ('880) 6 drachms.

Bromide of potassium 2 "

Water 6 "

Take of pyro, solution A 1 ounce,

" B 2 drops,

and increase the quantity of the latter as required up to twelve drops.

This, it will be observed, is quite the ordinary "Wratten" developer, except that a larger quantity of bromide is used.

Mr. Waite sends me a few platinotype prints from paper negatives taken in the summer and developed by the above. These prints speak for themselves, and are some of them as good in every way as they could be. They speak most eloquently not only for the method of development, but for the paper which Mr. Waite has used, and with great enthusiasm recommends.

One might go on in this way all night, but I think I have made good my title, and have produced a little batch of odds-and-ends which I thank you for so quietly listening to.

ABEL HEYWOOD, JUN.

HALATIONS IN NEGATIVES.

CHAPTER II.

THE second class of defects in bromised films, developed with alkaline pyro or ferrous oxalate solutions, may also be denominated a species of halation, but the effects produced must be traced to other causes than reflections from the back surface of the glass. Supposing that we are photographing fine white lines on a dead black ground, that we give a long exposure, and continue the development till the reduction of silver has reached the bottom of the film, it will be seen that the line is broader at the bottom than at the top. Or, again, *per contra*, if the lines to be represented are black on a white ground, it will be found that, by the same treatment in exposure and development, the lines will not be represented by clear glass as they ought to be, but will appear to be gradually shaded off from the white edges. Now it appears to me that this peculiar effect can be readily explained by the following process of reasoning based on well-known phenomena.

In the first instance, namely, a white line on a dark ground, the refracted white rays impinge on the surface of the film, say, in perfect focus, but in passing through it they are diffused laterally, so that they act chemically on all the sensitive particles with which they come in contact. The consequence is that, if the film be a thick one, a transverse section of the developed white line would appear broader at the base than at the top or surface of the film—in fact, pyramidal.

In the second instance, namely, a black line on white ground, the conditions are reversed, so that the light from the white surface, when the negative is developed, almost obliterates the line by excessive diffusion.

I have heard an attempt made to explain these phenomena by catalysis, or contact action; but I do not think we need call in the aid of a very mysterious force to enable us to explain what, I think, may be made quite clear by the simple diffusion of light through a translucent medium.

While on this subject, I may as well place on record a method,

devised by the late Major Russell, whereby an alkaline-developed bromide negative could be converted into a positive transparency. I have not tried gelatine plates, but the plan succeeds admirably with films prepared by collodio-bromide. When the picture has been developed to the greatest intensity of which it is capable, but not fixed, dissolve away the image by means of dilute nitric acid. If the acid be too strong it will attack the unaltered bromide; therefore, the best way to proceed is to begin with a little well-diluted acid, and to pour on and off the plate, gradually adding strong acid until the image is completely dissolved away and the film whitened. On holding the plate up to the light the picture shows as a transparency, the gradations being represented by different thicknesses of bromide of silver. If the collodionised film be now thoroughly washed, to remove the nitric acid and nitrate of silver, then flooded with tannin solution, exposed to daylight for a second or two, and again developed with alkaline pyro, a good and vigorous positive will be the result.

This experiment of Russell's is more interesting and curious than useful, because very few would feel disposed to spoil a good negative for the sake of a single positive. GEORGE DAWSON, M.A., PH.D.

CONTINENTAL PHOTOGRAPHY.

[Translations and Abridgments.]

PHOTOGRAPHING QUARRY EXPLOSIONS.

MONSIEUR G. BALAGNY writes that on April 21 last, at eleven o'clock, about twenty-six persons armed with cameras, and talking photographic "shop" surrounded the ticket office of the Argenteuil railway *en route* for Volambert; they had been invited by M. Albert Londe and MM. Lacauchie and Nitard, the directors of the Volambert gypsum quarries, to visit the latter to see what they could do in the way of photographing quarry explosions. M. Poyet, one of the artists of *La Nature*, had drawn up a card of invitation, full of humour and spirit, which M. Londere multiplied by photography. Each visitor was requested to bring his apparatus and six dry plates. The visitors alighted at Argenteuil, where they took luncheon, enlivened with Argenteuil claret, almost the only wine in France the production of which has, so far, been respected by the phylloxera.

Among those present were MM. Gaston and Albert Tissandier, M. Poyet, M. Maréchal, editor of *La Nature*, M. G. Ducom, M. Rolland, M. Darnis, M. Fabre, M. Geoffroy, M. Sauvé, M. Londe, M. Dessondeix, M. de la Bretonnière, M. Mermet, M. Hubert, M. Petit, MM. Arbey Brothers, M. Verdier, M. Renard, M. de Paumiat, M. Wallon, and Dr. Ranque.

At two o'clock precisely the whole party found themselves before the mass to be removed by the explosion, and beneath a burning sun took up their positions where they would, without placing themselves too near the mines. Two explosions had been arranged, and many photographers arranged themselves in a line before the first point indicated; several others bravely separated themselves from the group to take the profile instead of the face of the explosion. The artists in black thus dispersed with their three legs upon the white soil had a picturesque effect.

When all was ready, three successive regulation whistles were given, as the signal for firing the mines. A series of detonations followed, and in several seconds was a formidable outburst, which projected to about fifty metres in the air masses of rock, accompanied by stones and lumps of chalk of all sizes. No note was taken of how many exposures were made during this first explosion, but for the purposes of the present narrative more attention was paid to the second explosion, the photographing of which was the main object of the expedition. The block was an important one, and had to be removed all in one mass.

In general it is not easy to prevent the direct rays of the sun penetrating the dark slides, and on the present occasion the rays shone directly into the lines of the opening of the slide shutters, which was an objectionable feature, especially when the great sensitiveness of the plates is considered.

The photographers took up a new position; three blows of the whistle were sounded, followed by a number of subterranean detonations breaking up the galleries. The block, no longer held by the base, was dislodged in two portions, and was projected upon the ground in the middle of indescribable noise and smoke. M. Balagny took a negative which well renders the explosion and gives at the same time the strategical positions of the photographers. He also, by desire of the gentlemen present, took two instantaneous groups upon 27 x 33 flexible films.

At five o'clock all were on their way back to Paris, agreeing that a charming day had been spent, and that a society for photographic excursions for amateurs and professionals ought to be formed. With

a few additional remarks M. Balagny's article closes, without saying more as to the nature of the negatives obtained.—*Le Moniteur de la Photographie*.

THE HYDROSULPHUROUS ACID DEVELOPER OF MESSRS. A. & L. LUMIÈRE.

Notices of the hydrosulphurous acid developer recently used in France have already appeared in the English photographic press, but in a recent number of *Le Moniteur de la Photographie*, Auguste and Louis Lumière give somewhat extended details. They express their belief that even the shortest action of light produces a latent image upon a photographic plate, so that the thing to be done is to bring the said image into view; the reason why at present certain plates appear to be under exposed is, that a sufficiently strong developer to bring out the image is not applied. M. Maignan, pharmacist to the Bron Asylum, had suggested to them the trial of hydrosulphurous acid for the purpose, which they then found upon trial to be very efficacious. Hydrosulphurous acid until recently has never been isolated in a state of purity, and only a few years ago M. Schutzenberger discovered that it was probably obtained during the action of aqueous sulphurous acid upon zinc. The solution takes a yellow colour all at once, due to the formation of hydrosulphurous acid, then it quickly loses its colour because of the decomposition of the latter, hyposulphite of zinc being formed, accompanied by a deposit of sulphur.

The fugitive nature of hydrosulphurous acid, accelerated also by contact with the air, renders the employment of it as a developer difficult, and makes it necessary to effect the development in the midst of the reaction; this condition is indispensable because the products of oxidation evolved during the complete reaction have the property of destroying the latent image. The best results have been obtained by using a saturated solution of sulphurous acid, and throwing into it the smallest possible quantity of zinc. Unhappily the nausea provoked by breathing the poisonous gas, the heating of the liquid, and the production of a veil of sulphide of silver due to the liberation of free sulphur, are considerable obstacles to the employment of this mode of development. It is likewise true that results obtained with it have surpassed those obtained with developers previously known, and give incontestable proof, say the authors, of the power of this new agent of photographic reduction.

THE ACTION OF LIGHT ON SALICYLIC ACID.

Dr. Phipson remarks that it has been stated that aqueous solutions of salicylic acid, such as are often employed in medicine and as a disinfecting agent, are altered by exposure to the solar rays in such a manner that any bottle containing a weak solution of the acid, and which is placed where solar light falls upon it several hours a day, loses all its acidity sooner or later, so that one or two drops of perchloride of iron then no longer produce in the solution their characteristic reaction. He himself has found that a solution of salicylate of lime, made with pump water, and exposed to light, is equally decomposed in a short time, and that at the end of several weeks the bottle contains a great quantity of white and brown filaments, consisting of algae and bacteria.—*Le Moniteur de la Photographie*.

CLEARING SOLUTION.

When a negative is slightly veiled, perhaps because of the use of ordinary water for developing and other purposes, the plate should be thoroughly washed, and then dipped into the following solution for a few instants only:—

Water	100 parts.
Ferrous oxalate	2 "
Alum	8 "

The negative will be cleared up in an admirable manner, and the whites left transparent.—*Photographisches Archiv*.

PHOTOGRAPHING BY GASLIGHT.

[A Communication to the Photographic Society of Philadelphia.]

THERE is nothing novel, nothing strange in the fact that certain salts of silver are sensitive to the moderate amount of actinic force contained in the flame of ordinary illuminating gas. Quite early in the reign of collodion some excellent work was accomplished by the use of such illumination in photographing interiors and dark places, but the difficulties attending the operation, the length of time required for exposure, and the consequent danger of the drying of the plate, did not contribute much to the popularity of the process. In fact, it was used only in extreme cases; frequently, merely to show the possibilities of the method.

With the advent of the extremely sensitive bromide of silver gelatine

dry plate, one might suppose it would have advanced in favour; but the superiority in power, convenience of application, and cheapness of the electric light, considerably depressed the general interest for it as an artificial source of illumination.

Portraits have been successfully made by gaslight, and even apparatus devised to utilise to the best advantage the force of the flame, but I think it may be safely said that at present no gallery in the world employs it.

Our object is not to show the superiority of gaslight over the other artificial illuminators, though we do think, had it been allowed in the struggle for existence to appropriate more of scientific and general interest, it would have differentiated much further, inasmuch as it possesses certain inherent good qualities which its more favoured rivals cannot claim.

We merely wish to call attention to its great value in photographing interiors. Indeed, in this province of the art it possesses advantages over daylight in softness of the general effect.

In our experiments we did not use any apparatus whatever, not even reflectors, employing merely the light of the ordinary burners protected by ground-glass globes.

The source of light was not intense—five bat-wing burners of a chandelier suspended from the centre of the room, 15×30 feet, the camera being placed at either extremity, and hence necessarily directed towards the light, but low enough to prevent the flames appearing on the ground-glass. A Ross' rapid symmetrical lens, six-inch focus, was used, and exposures given from ten to twenty minutes. The results will be shown at the close of the meeting by means of slides in the lantern. We imagine no one would be able to distinguish them from good interiors taken by daylight.

We have photographed the same room when illuminated by diffused sunlight, but have not obtained results as uniform in lighting. Daylight gave more violent contrasts, the darker portions of the room lacking much in detail, while the highly illuminated parts were too intense. It is especially on account of the evenness and general distribution of the light that we prefer gas to ordinary daylight.

Its advantages over burning magnesium wire are even greater. Our experiments with this pure white illuminator gave very harsh contrasts in light and shade, although we sought to modulate its action by tissue screens, and by distributing the illumination as much as possible. We did not try the electric light.

The exposures of ten minutes with gas lacked somewhat in detail, showing under time; but those of twenty minutes, as you will see, are pretty rich in detail even in the deep shadows. The plate we employed was, of course, the highest sensitizer number we could secure—some of Cramer's recent extremely sensitive brands. With the twenty minutes' exposures we developed with pyro and potash—of the ordinary stock solutions:—

Pyro	2 drachms,
Potash	1 drachm,
Water	2 ounces,

which sufficed to bring up all the detail, and to give good density without any extra addition of accelerator, which, we think, demonstrates the truth that an evenly-lighted subject really requires less time with a moderate light than one violently illuminated with a strong light.

While making these gaslight photographs, we were induced to try the action of the yellow gaslight in rendering the colours with orthochromatic plates.

Carbutt B plates and Seed plates were first placed in a preliminary bath, consisting of

Ammonia	1½ drachms,
Water (distilled)	7 "

and allowed to remain for a minute or two. They were then transferred to the orthochromatic bath, made according to the formula given in a package of Flandreau's orthochromatic solution, kindly sent by the Scovill Manufacturing Company:—

Water	5½ ounces.
Erythrosine	1½ drachms.
Ammonia	2 "

Here they were rocked for a little over a minute, taken out, drained, and dried in an ordinary drying closet.

They were exposed upon objects of blue, yellow, red, and green colours without the interposition of the yellow screen, making use of the light of a coal oil lamp with a reflector placed near the objects, in addition to the light of the gas flames. The time of exposure with the B plates was fifteen minutes; with the Seed, two minutes. The ordinary developer of potash and pyro was used. I was troubled much with fog, especially with the Seed plates, whose sensitiveness was probably affected by the ammonia employed, but the results ob-

tained in the rendering of the yellow and orange were surprising. I have a couple of prints, one from the fogged Seed plate, two from the clear Carbutt plates, which show this remarkable action. The oranges in the basket were very orange in colour, while the flowers were hyacinths of the palest blue, almost white—nevertheless, the deep so-called adactinic colour of the fruit is rendered as a high light, as in nature, only a few degrees below the flowers.

In the other picture, the long-necked vase is of a bright chrome yellow colour—which ordinarily is translated dark, the vase immediately behind it is ultramarine blue, the large urn light green, while the recumbent vase is vermilion. This last has scarcely taken better than with an ordinary plate.

The erythrosine, therefore, would seem to depress the action of the blue, and to render the yellow, orange, and green in their true relations, but not the reds.

Probably it would make an excellent plate for the yellowish greens of spring foliage.

I made some attempts at portraiture with ordinary plates by gaslight, and I show them merely to call the attention to the possibilities of modelling with light and shade.

I found, by using a small hand reflector of eardboard and a shader, one might, if possessed of the skill, model in an artistic manner the head, by directing the light and shade to any desired part. Of course means could be devised to shorten the time of exposure to less than a minute, and by keeping the reflector and shader in gentle motion, any required degree of light and shade could be secured, and much softness given to the image.

One recommendation has photography by gaslight. It is independent of time and season and state of weather.

We could not help noticing how strange it was for us to be taking pictures in a warm, cosy room, while without the wind and the rain were striving for mastery.

JOHN BARTLETT.

THE FOCUS OF LENSES.

[A Communication to the Camera Club.]

A QUESTION is asked in last month's *Proceedings* as to the best way of ascertaining the focal length of a doublet lens. I think it will be of greater use to our members to give a short *résumé* and critique on the various methods that have been proposed at various times for ascertaining the focus, rather than giving any particular cut-and-dried formula. Let us suppose that we are photographing any subject—say, a candle: this candle, called the *object*, is a spot of light emitting rays in every direction; of these, a certain quantity, in shape a cone, fall on the surface of the lens, which possesses the property of seizing them, and re-forming on the ground-glass a representation of the candle, called the *image*. We have then two definite points, the candle, or object, on one side of the lens, and the representation on the ground-glass, or image, on the other side. Now, these two points are called the conjugate foci of the lens, and the distances from the optical centre of the lens to these foci are called the conjugate focal lengths.

Now, we know that if an object, in our case a candle, is near to the lens, the camera has to be racked out considerably; if we bring the object nearer, we have still more to increase the distance between the lens and the image; if, on the contrary, the object be removed further away, the distance is shortened, until at last we find that, arrived at a certain distance, no further shortening is necessary, for the candle, and every object beyond it, is sharply represented. The reason of this is that the angle of the cone of rays coming from the object and falling on the lens has become so exceedingly small, that the rays are virtually parallel; and, although the position of the conjugate focus on the object side may be moved further and further off from the lens up to infinity, that of the conjugate focus on the image side does not alter. This immovable focus is then called the principal focus of the lens, which we can define as the focus of parallel rays, and the distance from this point to the optical centre of the lens is the focal length of the lens.

The principal focus is also sometimes called the solar focus, because the sun is so far off that its rays are parallel, and the point where its image is formed is the solar focus of the lens. The measurement of this distance would, of course, give us our focal length in a very easy manner, but, unfortunately, it is a matter of considerable labour to find the optical centre of a lens, as it depends upon the radii of the curvature of the lens. For a plano-convex lens, however, this point lies on the curved surface, and the focal length can be easily found by measuring the distance between the curved side of the lens and the image of the sun.

When speaking of lenses formed of two or more combinations, the focus is spoken of as the equivalent focus. This only means the solar

focus of the combination of lenses. It is called equivalent focus, because a single lens of such a focus would produce results equivalent to the combination of lenses.

LYONEL CLARK.

(To be continued.)

ON RED AND PURPLE CHLORIDE, BROMIDE, AND IODIDE OF SILVER; ON HELIOCHROMY, AND ON THE LATENT PHOTOGRAPHIC IMAGE.*

Silver Carbonate may be roasted in the same way as silver oxide, and yields a similar product. By heat its colour changes from yellow to black; it is probable that the carbonic acid is driven off at a lower temperature than that at which oxide is reduced to silver, and that with it escapes part of the oxygen. The residue is converted by H Cl into deep red chloride.

Action of Various Metallic Oxides on Silver Oxide.—If we precipitate ferrous oxide with potash and add to this silver oxide, or what amounts to the same thing, if we add to ferrous sulphate potash in excess and pour over this silver nitrate solution, the silver oxide separated by the potash is partly reduced by the ferrous oxide, and when treated with H Cl forms red chloride, the intensity of the colour of which depends within certain limits on the amount of reduction of the silver oxide.

Similarly if we treat solution of manganous sulphate with excess of potash and then add silver solution, we get an analogous reaction, except that it is much weaker and heat is necessary.

With chromous oxide the action is still weaker, but evident. With cobaltous oxide it is scarcely perceptible without heat and long continued action.

Action of Ferric Chloride on Metallic Silver.—It has been long known that silver was blackened by ferric chloride, and this action has been proposed in the textbooks as a means of obtaining subchloride, for which it is quite unsuited.

Ferric chloride acts on silver much as sodium hypochlorite does, but less rapidly. With hypochlorite the action is complete in a few hours or often in an hour or less; with ferric chloride one or two days are required before the product ceases to yield silver to hot dilute nitric acid. In both cases the action appears to be alike in this: that no subchloride is finally left uncombined with normal chloride.

The product is an intensely dark purple-black, when the action takes place in the cold. With heat continued for many hours, ferric chloride can be made to attack the purple salt and gradually convert it into Ag Cl. With a strong solution in large excess kept at or near 212° Fahr. for sixty hours the colour was gradually reduced to pink and finally to a dingy pinkish grey. Pure white cannot be obtained, as it can by aqua regia.

In order to observe more exactly the course of the action, a strong solution of ferric chloride was allowed to act on reduced silver in fine powder for four minutes, and then a fresh portion (always in large excess) for the same time. Analysis showed that at this stage of the action the material contained:—

Ag (determined).....	76.07
Cl (by difference)	23.93
	100.00

If we suppose that all the silver was combined with chlorine, the constitution of the substance would be:—

Ag Cl	92.49
Ag ₂ Cl	7.51
	100.00

But this was probably not the case; there was almost certainly free silver present and consequently a less proportion of subchloride. Another specimen, treated repeatedly with hot acid until every trace of free silver was removed, was found to contain 1.52 per cent. of subchloride, colour purple. Another similarly treated contained 7.3 per cent. subchloride.

Action of Nitric Acid on Silver Subchloride.—When freshly precipitated and still moist subchloride of silver is treated with nitric acid, a sharp effervescence accompanied with a disengagement of red fumes, sets in; presently the strong red colouration of the photochloride appears and the action ceases. This production of the red and not the white chloride in the decomposition of Ag₂ Cl is precisely what might have been expected, for when Ag Cl is formed in the presence of Ag₂ Cl more or less combination always takes place.

The action is interesting in this respect: the Ag Cl first formed is at the moment of formation in presence of all the yet undecomposed portion of Ag₂ Cl, and whatever part it combines with is removed from the action of the acid. It would therefore seem probable that this method would be one of those that yielded a product having the largest proportion of Ag₂ Cl, but analysis showed that different specimens were extremely variable—of those analysed, one contained 8.62 per cent. of Ag₂ Cl, another 6.56, and a third 1.96. All that analysis can do with such substances is to fix the limits within which they vary. The quantity of subchloride left after treatment with nitric acid depends partly on the strength of the

acid and the time for which it is allowed to act, but also to some extent on variations in the resistance of the substance itself. These specimens were of shades between rose and purple.

The colour of any particular specimen is always lightened in shade by abstracting Ag₂ Cl from it by continued boiling with nitric acid. But as between different specimens, especially when formed by different reactions, it by no means follows that the darkest in colour contains the most subchloride.

Argentous chloride when treated with sodium hypochlorite yields a purple form of photochloride. A specimen so treated contained 2.57 per cent. of Ag₂ Cl.

Action of Cupric Chloride on Silver.—When metallic silver is submitted to the action of either cupric chloride or, what gives the same result, a mixture of copper sulphate and ammonium chloride, an action takes place very similar to that of ferric chloride, but more energetic, and the resulting red chloride is apt to be lighter in shade, though in this respect it varies very much. As in the case of ferric chloride this action of cupric chloride on silver is given in some textbooks as a means of obtaining argentous chloride, for which purpose it is as little suited as the iron salt.

As a mode of obtaining red chloride it is not to be recommended. It is troublesome to get the copper completely removed. A specimen analysed was found to consist of white chloride with 6.28 per cent. of subchloride.

Action of Protochlorides on Silver Solutions.—*Cuprous Chloride.*—When very dilute solution of silver nitrate is poured over cuprous chloride, a bulky black powder results, which by boiling with dilute nitric acid turns red, the acid extracting little or no silver.

Ferrous Chloride.—When silver nitrate is dissolved in a slight excess of ammonia, and this solution is poured into a strong one of ferrous chloride, there results a precipitate which is sometimes greyish, sometimes olive black. By washing with dilute sulphuric acid, this product becomes brownish purple, and brightens by boiling with dilute nitric acid. It was found to contain 4.26 per cent. of subchloride.

Photochloride by Action of Hydrogen.—When hydrogen is passed over argentic citrate at 212° Fahr., as in Wöhler's process, there results a black or dark brown powder consisting of argentous citrate, metallic silver, and perhaps other substances. When this is treated with hydrochloric acid and subsequently with nitric, the resulting product is photochloride, the characteristic colour of which sometimes appears as soon as the H Cl is added. But more frequently the material after the action of H Cl has precisely the appearance of silver reduced in the wet way, and the red colour appears only after treatment with nitric acid. Even cold dilute acid (by some hours' contact) will isolate the red chloride; boiling acid does so at once.

Colour, beautiful purple. A specimen analysed was found to consist of normal chloride combined with 3.11 per cent. of subchloride.

Photochloride by Action of Potash with Oxidisable Organic Substances.—There is no better method of obtaining photochloride than by acting on a salt of silver with potash and certain organic substances. Milk sugar, dextrine, and aldehyde, give particularly good results. Milk sugar acts rapidly, dextrine slowly. Other substances with which, combined with potash, I have obtained chloride, are:—Gum, tannin, gallotannic acid, manna, glycerine, alcohol, carbolic acid, &c. The number might, doubtless, be indefinitely multiplied. After the action has reached a proper stage, which with milk sugar is apt to be in less than a minute, and with dextrine may take half an hour, H Cl is added, whereupon the precipitate changes in appearance, but does not exhibit its characteristic colour until after boiling with nitric acid; the best result is obtained when the precipitate, after addition of H Cl, has a rich chestnut brown shade,* which by nitric acid changes to shades of purple and burnt carmine, when milk sugar, dextrine, or aldehyde has been the reducing agent. When the salt of silver employed has been the chloride, of course treatment with H Cl is superfluous.

A specimen, obtained by acting on silver nitrate with potash and dextrine, was found to contain 2.26 per cent. of subchloride. Another, obtained with silver nitrate, potash, and milk sugar, contained only 0.34 per cent. As in former instances, these determinations are useful only in indicating the extreme variability of these substances and their approximate limits of composition.

Other Reactions Leading to the Formation of Photochloride.—A few more instances are here added, indicating the variety of ways in which this product may be obtained.

The following is an interesting reaction:—If a solution of ferrous sulphate is made strongly acid with H Cl and solution of silver nitrate added, the silver is thrown down as white chloride. But if to the silver solution is first added a little ammonia, enough to redissolve the oxide, but much less than enough to neutralise the acid added to the iron solution, then on pouring the silver solution into the iron the silver falls as red chloride. So obtained, it has at first a dull purple or shade, but by purification, as before described, a good product is obtained. This method, however, scarcely tends to the production of the splendid copper red shades of colour that are got by acting on silver chloride dissolved in ammonia with ferrous sulphate, and then adding dilute sulphuric acid. The shade of colour shown by any particular specimen is always of

* A specimen in this stage, and before treatment with nitric acid, was found to contain 32.68 per cent. of silver, showing it to be a mixture of metallic silver with chloride and subchloride.

interest, because, as before mentioned, it modifies the effect exerted upon it by the spectrum.

Potassio-ferrous Oxalate.—The now well known "oxalate developer," which I described in this Journal some years ago, throws down from silver nitrate a black powder; this precipitate treated with H Cl scarcely alters in appearance, but washed and boiled with dilute nitric acid changes to a deep purple.

Pyrogallol is capable of leading to the formation of photochloride. When ammoniacal solution of silver nitrate is poured into solution of pyrogallol in water made strongly acid with H Cl, in such proportion that the mixed solutions remain strongly acid, there falls a greyish product, which by washing and treatment with hot dilute nitric acid becomes bright pink.

Ferrous Oxide differs essentially in its action on silver solutions from ferrous sulphate. A silver nitrate solution added to one of ferrous sulphate precipitates grey metallic silver. But if potash or soda is first added to the ferrous solution, and then silver nitrate, followed by H Cl, the red chloride is formed abundantly. This reaction is similar to that already described, in which an ammoniacal solution of a silver is added to one of ferrous sulphate.

To the same class of reactions belongs the following: Silver carbonate with excess of sodium carbonate is thrown into solution of ferric sulphate, and after standing a few minutes H Cl in excess is added. The silver is converted into red chloride.

It seemed possible that silver itself might be made the means of reducing its chloride. The experiment was made in this way: Freshly precipitated and still moist chloride was intimately mixed with metallic silver in fine powder and a little water. This was heated till the water boiled and nitric acid was added. After the action was over the chloride had assumed a deep pink colour. A similar result is obtained without the aid of heat, but the resulting colour is much paler.

Analogous to this is the following: When a cake of fused silver chloride in a crucible is reduced with dilute sulphuric acid and zinc, if the reduction is interrupted when not quite finished, and the metallic silver is dissolved out with hot nitric acid, the residue of silver chloride will be found to be pink.

When H Cl is brought into contact with Ag together with an oxidising agent, such as a bichromate or permanganate, it gives rise to formation of coloured chloride. These I have not specially examined, but there can be little doubt that they are identical in nature with the foregoing. So, too, when silver in contact with mixed potassium chloride and chlorate is cautiously treated with dilute sulphuric acid.

The reactions above described will serve to show under what a vast variety of conditions the photosalts are formed. Most of the methods here described represent each a whole class of reactions, all resulting in the same general way, and these classes might doubtless be largely added to. Almost any silver solution brought into contact with almost any reducing agent, and then treated with H Cl, gives rise to the formation of photochloride. Almost any chlorising influence brought to bear on metallic silver has the same result, or when silver is brought into contact with almost any oxidising agent and H Cl. It may be said without exaggeration that the number of reactions that lead to the formation of photochloride is much larger than that of those leading to production of normal chloride.

Reactions of Photochloride.—Exposed to ordinary diffuse light all the bright shades of silver photochloride quickly change to purple and purple-black. The darker shades are more slowly influenced.

Mercuric chloride gradually changes it to a dirty white. Mercuric nitrate dissolves it easily and completely, but apparently with decomposition, as it can only be recovered as white chloride.

Potassic chloride seems to be without effect. Potassic bromide soon converts it to a dull lilac, which at the end of twelve hours showed no further change.

In contact with potassic iodide the colour instantly changes to blue-grey; this change is produced by a quantity of iodide too small to dissolve even a trace of silver; the filtrate is not darkened by ammonium sulphide. With a larger quantity silver is dissolved abundantly. By acting with renewed iodide solution, the substance continually darkens and diminishes until only a few black points, barely visible, are left.

Treated with dilute solution of potassium chlorate and H Cl, the red substance gradually passes to pink, to flesh colour, and, finally, to pure white.

The action of heat on the photochloride is very curious; its tendency is generally toward redness. Specimens appearing quite black are rendered distinctly purple or chocolate by heating to 212° Fahr. in a drying oven. Often when the substance first separates by addition of H Cl, it is pure grey; this grey will often be changed to pink by simply heating to 212°. (This happens when a grey form is produced; if the greyiness is due to admixed metallic silver, it is only removed by boiling with nitric acid.)

The somewhat surprising change of colour which is often seen when the crude substance is boiled with nitric acid (sometimes from dull, dark grey to crimson) is due to three concurrent actions: that of the mere heat, the removal of the silver, and the breaking up of uncombined subchloride.

It is not possible to dissolve out the normal chloride by a solvent like ammonium chloride from the photochlorides, leaving the subchloride

behind. When red chloride is boiled with successive portions of strong solution of ammonium chloride in large excess, the material gradually diminishes until, if the operation is continued long enough, there remains a small residue of a warm grey colour, which consists of metallic silver, and dissolves without residue in nitric silver.

If sodic chloride is substituted for ammonium chloride, the same result follows, except that the operation is greatly more tedious. If persevered in until the hot solution no longer removes traces of silver chloride, the residue consists of nothing but metallic silver.

Action of Light on Normal Silver Chloride.—When silver chloride precipitated with excess of H Cl is exposed to light, it becomes with time very dark. Cold, strong nitric acid 1.36 s.g. extracts a trace only of silver.

The principal action of light on Ag Cl (precipitated in presence of excess H Cl) consists in the formation of a small quantity of subchloride, which enters into combination with the white chloride not acted upon, forming the photochloride, and thus is able to withstand the action of strong nitric acid. At the same time a trace is formed, either of metallic silver or of uncombined subchloride, it is impossible to say which. After a certain very moderate quantity of photochloride is formed, the action of light seems to cease. The cessation has been noted by many observers, perhaps most exactly by Dr. Spencer Newbury.

The nature of the product formed by the continued action of light on silver chloride seems to support the conclusion that the subchloride is combined with the whole of the normal chloride after the manner of lakes rather than in equivalent proportions. If the latter were the case, it seems probable that the continued action of light would extend to much greater decomposition than it is found to do.

The action of light in the formation of the so-called latent image will be examined in the second part of this paper.

PHOTOBROMIDE AND PHOTOIODIDE.

It has been already mentioned that bromine and iodine form with silver combinations in all respects analogous to those of chlorine. A more particular account of the bromine and iodine compounds must wait for the next succeeding number of this Journal; here it can only be mentioned that these substances are formed much in the same way as the chlorine compound. They are less stable than it, and consequently the number of reactions that lead to their production is somewhat more limited. Each, however, is formed in a great variety of ways, and with the same ease as the chloride. In colour they are for the most part indistinguishable from it, but exhibit different reactions.

RELATIONS OF PHOTOCHLORIDE TO HELIOCHROMY.

The photochloride was examined both with the spectrum and under coloured glass. The rose-coloured form of photochloride was that which gave the best effect. In the violet of the spectrum it assumed a pure violet colour, in the blue it acquired a slate blue, in green and yellow a bleaching influence was shown, in the red it remained unchanged. The maximum effect was about the line F, with another maximum at the end of the visible violet, less marked than the one at F.

Under coloured glass the colours obtained were brighter; under two thicknesses of dark ruby glass the red became brighter and richer. Under blue glass some specimens gave a fair blue, others merely grey. Under cobalt a deep blue was easily obtained, and under manganese violet, a fine violet, very distinct in shade from the cobalt. Green produced but little effect—yellow was sometimes faintly reproduced but rarely. But the yellow glass of commerce, even the dark yellow, lets through portions of nearly the whole spectrum, as can readily be seen by testing it with the spectroscope.

The dark purple forms of chloride do not give as good results as the rose and coppery shades. These last have many points of resemblance with the material of Becquerel's films, resemblance of colour, probably of composition, as far as we can judge of the constitution of those films from their origin—they were far too attenuated to admit of analysis, and resemblance in the curious way in which their colour is affected by heat, so that the conclusion seems inevitable, that they are at least closely related.

There is certainly here a great and most interesting field for experiment; hardly any two specimens of photochloride give exactly the same results with coloured light, and this suggests great possibilities. There is the very great advantage in this method over any previous, that the material is easily obtained in any desired quantity, and in a condition most favourable for experiment.

The action of light on photochloride can be a good deal affected by placing other substances in contact with it. Any substance capable of giving up chlorine seems to influence the action somewhat; ferric chloride often acts favourably, also stannic and cupric chlorides.

Evidently an important point in all heliochromic processes is that as white light must be represented by white in the image, it is an essential condition that white light must exert a bleaching action on the sensitive substance employed. Red chloride does not bleach but darkens in white light, but the property of bleaching, to a very considerable extent, may be conferred on it by certain other chlorides, and particularly by lead chloride and zinc chloride. This I look upon as very important.

Another matter of interest is exaltation of sensitiveness, and this I find is accomplished in quite a remarkable way by sodium salicylate, the presence of which at least trebles the action of light on these substances. And probably on others.

I am persuaded that in the reactions which have been here described lies the future of heliochromy, and that in some form or other this beautiful red chloride is destined to lead eventually to the reproduction of natural colours.

M. CAREY LEA.

—*The American Journal of Science.*

WHERE I WENT WITH THE CAMERA.

NO. VII.—COLOGNE AND BRUSSELS.

LEAVING Berlin I came on to Cologne. After the cathedral, the bridge of boats, and one or two other stray subjects, I did not find much photographic work here. The streets generally are narrow and winding, and most of the houses are not well built.

The cathedral as a fine subject is known all over the world, both for its extent and its beauty. The time it has taken to build is also a very general part of the conversation when talking of this charming Gothic edifice. It was begun about 1250, and is not yet finished. It is shrewdly suspected that those interested are in no hurry to have the work completed, for it must be a considerable revenue to the church showing it off as it is, and demanding fees for everything to help to finish the good work. A frame to see the relics, a frame to go up the towers, a frame for this and a frame for that all over the place. It means a lot of money, for it is a good show and is always well attended. I did the mounting of the tower, but the day was hazy and unpropitious.

The Hotel du Nord, at which I stayed here, was certainly the best appointed and best all round house of any hotel on my route. I got one or two very good negatives from my bedroom windows.

It is stated that there are over thirty manufacturers of the genuine Eau de Cologne established in this city. That manufacture must be a pretty open secret.

One of the prettiest sights I saw in Cologne was the market-place in the morning, filled with busy life and bright, shifting colours. The square looked like a scintillating gem in a dark setting. I got a picture of the scene—a very pleasant memory.

I next came to Brussels, which is a very beautiful city, and, from a photographic point of view, one that would do your heart good to see. Streets, squares, promenades, and handsome buildings in abundance and to choose from. I found quite a number of studies in the market-place, in which is situated the Hotel de Ville or Town Hall, a very old but handsome building forming one side of the square. This hall is rich in relics and curiosities, and is open to visitors at a charge of half a franc. One thing that is pointed out particularly to the visitor here is the painting of a female on the roof of one of the state rooms. She has a trumpet to her mouth, and no matter where you turn, or what part of the room you go to, the figure seems to turn also, and the trumpet is always towards you. The effect is rather startling, the whole body seeming to alter in position as you walk round.

The tower of this hall is 360 feet high, and one of the grandest panoramas imaginable is obtained from the top. I got some good general views from this tower. Away up in this place, far above the noise of the seething city, a boy sat waiting to take the tickets from visitors when they came up. I suggested to him that his must be a very solitary life up there; but he had got quite used to it, and sat there reading hour after hour, perfectly satisfied with the monotonous occupation. On the Sunday morning I saw a novel sight in the market-place. This was a bird-market. Birds of all kinds in cages being bartered and sold—thousands on thousands of birds holding high concert as the sellers did a busy trade. This market is allowed a certain number of hours on the Sunday morning; when the time is up it is cleared. When the hour comes for closing it seems as if a magic wand had been passed across it, for presto! change! and the square is empty almost in a minute.

On this same Sunday I visited the Church of St. Gudule. When listening to the service there you may guess my surprise when a man came up to me and tended me his business card and asked me if I would be good enough to go and see the lace factory, that it was only a short distance from the church and well worth seeing. This is pushing business and no mistake, thought I. It was almost as bad as the Yankee who offered to supply a congregation with hymn-books free if they would allow him to put his "hat" advertisement on the fly-leaf.

The Palace of Justice in this city stands out as an edifice unique and alone, both as regards position and magnificence. In the midst of hundreds of splendid and beautiful buildings this palace towers above them all.

When in this city I visited the Wiertz Picture Gallery. It is not much talked about, but, knowing something of the life of the artist, and the eccentric form of his genius as displayed in his works, which for size, conception, and execution are most wonderful, I had a great desire to see it. Wiertz seems but to have had one concentrated passion all through his life—from his earliest boyhood up, and that was to attain glory, to gain a fame that would live for centuries. His father used to delight to dwell upon this theme, and the boy hearing it desecrated on and magnified from every point of view, it became a second nature to him, and renown became the object of his life. When other children were only thinking of toys, Wiertz was covering his copybooks with crayon drawings, or carving out all sorts of grotesque figures with his pocket-knife. On one occasion he carved a frog so true to nature that at first sight it seemed a living thing. The chief of police when visiting his father was shown this frog, and it

astonished him so much that he talked about it everywhere. This trivial incident decided his fate, for this story of the frog coming to the ears of M. Paul Maibe, a gentleman much interested in art subjects, visited the child and was charmed with him. He took him to his house, and afterwards sent him to school; he also gave him lessons in drawing. At the age of fourteen he was sent to be taught sculpture, drawing, carving, and engraving. At Antwerp he studied under Herreyns and Van Bree. In 1821, when he was but fifteen years of age, King William gave him a pension of 140 florins, rising to 300 florins a year. This good service also was due to the kind representation of M. Paul Maibe. On this income, averaging 200 florins a year, he managed to live, and, following the counsels of his father, he allowed himself no relaxation, but worked steadily and unceasingly on to the one point—to be a great painter. At the age of twenty, when recommending a pathway in life to young painters, he said, "In a time when mechanism is preferred to expression, you must have the courage to imitate the great Poussin, to paint for posterity, and struggling against the bad taste of the time know how to remain poor in order to know how to become great," adopting this stoical idea for himself. Some time after he wrote a friend, "To paint pictures for glory, and portraits for pot-boilers, is the occupation of my life."

In 1828 he competed for the prize of Rome, and in 1832 he was crowned. Now he could visit Italy; now he could study the great masters; now he could plan a work for himself. He wished to measure himself with Rubens or Michael Angelo. For his subject he went to Homer's *Iliad*—at this time he lived in the country of Homer, and revelled in his works—the outcome of which was his first great work, a picture thirty feet broad by twenty feet high, entitled *Patroclus—the Greeks and Trojans*. In six months it was finished and exhibited in Rome. Old Thurlwaldsen, when viewing the picture, exclaimed, "This young artist is a giant." This picture astonished the art world. The journals wrote him up, and the Art Society of Antwerp offered Wiertz a banquet; but the glow of this first dawn of glory was not broad enough for him, he had not yet reached the height he wished to attain. So he resolved to send his large picture to Paris. But, alas! at this time misfortune seemed to follow him. The picture only missed being seized by the Custom House officers, then it got storm stayed, and reached Paris too late to be in time for that year's exhibition. He got it in the following year, 1839, and it was placed in the Salon of Honour; but it was hung so high, and in such a bad light, that the subject could not be made out by any one. This failure made him begin to despair; for a little he seemed to doubt his genius, but only for a little, for shortly after this we find him at Brussels looking round for some place large enough to hold the size of canvas he wanted to paint. He was unsuccessful in his search for a long time. At last he came upon an old, empty mill that he turned into a studio. In this place he painted that picture which placed him in the first rank of the artists of his country—*The Triumph of Christ*. The size of this picture was forty feet by twenty-five feet. The grandeur of the conception, and the style and treatment of the subject, were considered entirely new. He lived to paint. The necessities of life only did he allow himself; idleness was unknown to him. He painted portraits to live, he painted pictures for posterity. In 1850 he had seven large pictures. The Minister of the Interior offered to build him a studio large enough to hang these, and space for his future works on condition that these seven pictures would be the property of the State, and that future works would be bought as arranged. He agreed. A building vast in size was completed and the pictures placed in it. Now had he attained what he had so long desired, and in his new studio he settled down to realise the dream of his life—the glory of a name. Shortly after this he invented a new medium for painting—a kind of flat or matt oil paint. Pictures painted by it could be seen in any light, as it had neither glaze nor reflection. He published the details, and other artists have made pictures by the process with marked success.

In the midst of mighty unfinished projects, and with a seeming glorious future before him, Wiertz passed away. He was only a few days ill. At first the doctors did not anticipate anything serious; but he grew gradually worse, and died on June 18, 1865, being fifty-nine years of age.

His last deposition was written by himself, and was very concise, thus:—

"I nominate my friend, Charles Potvin, my sole legatee."

But his friend knew exactly what he wanted done, and he faithfully attended to it. He was to offer the collection of pictures to the Government on the conditions that the collection was never to be broken up nor sold, but to be kept in its entirety as the Wiertz Gallery, and if they accepted his conditions he committed himself to the good faith of his country.

The terms were accepted, and the gallery is now one of the national institutions, and we, the visitors, are the posterity Wiertz dreamed of.

If in this city, do not miss seeing this collection of pictures.

MARK OUTE.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

THE local Committee held a meeting at Glasgow on May 26. Mr. John Stuart, Chairman of Committee, presided. Final arrangements were made for the Convention meeting on July 4.

It was arranged to hold evening meetings from Monday to Friday inclusive, with the exception of Thursday night, which will be left free. Six excursions were agreed upon, giving a choice of two on Tuesday and two on Wednesday, leaving one for Thursday and one for Friday.

The details of these meetings and excursions will be given in a programme of the week's proceedings. This programme will be in the hands of members of the Convention some time before the meeting.

Attention is directed to the circular issued by the Exhibition Committee.

The importance and success of the Exhibition is already assured by the number of requests for space sent in by professional and amateur members of the Convention, and every member who possesses anything whatever of interest to the craft should take this excellent opportunity of exhibiting.

The following is the circular alluded to:—

"PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

"At Glasgow, week commencing July 4, 1887.

"EXHIBITION.

"The Exhibition Committee issue the following information to intending exhibitors:—

"1.—The Exhibition shall form part of the Convention meeting; is not competitive or public in its character, and is intended for members and their friends only.

"2.—The Exhibition is intended to include every class of photographic work and apparatus, and exhibits are requested from any member, whether professional, amateur, manufacturer, or dealer. Members are solicited to show anything whatever of special interest, whether old or new.

"3.—Exhibitors must be members of the Convention.

"4.—The Committee will be ready to receive exhibits on 14th June, and not later than 24th June.

"5.—All packages to be addressed 'Photo. Convention, Institute of the Fine Arts, 175, Sauchiehall-street, Glasgow.'

"6.—All forwarding charges to be prepaid by the sender.

"7.—Exhibitors are requested, on forwarding goods, to advise the Local Secretary, and to enclose address label for return.

"8.—Exhibitors are requested to attach to all exhibits a card, describing process, &c., and giving name of exhibitor. These cards to appear in a prominent position, as it is not intended to prepare a catalogue.

"9.—For the convenience of exhibitors at a distance from Glasgow, the Committee will repack and forward goods after the meeting.

"10.—Local exhibitors are requested to remove their exhibits within three days after the close of the Convention.

"11.—The Committee will take every reasonable care of exhibits, but they cannot undertake any responsibility for loss or damage.

"JAMES DAVIE, Hon. Local Secretary,

"36, Darnley-street, Pollokshields, Glasgow."

Our Editorial Table.

GUIDE TO THE SCIENCE OF PHOTO-MICROGRAPHY.

By E. C. BOUSFIELD.

London: Kent, Paternoster-row; and Sharland, Thavies Inn.

In this *brochure*, which contains sixty-nine pages, Mr. Bousfield very skilfully and ably goes into the practical details of photo-microscopy, treating all departments fully without being prolix. For the ordinary run of work he thinks that as to the source of light there is nothing at all equal to a good paraffine lamp with a flat-flame burner, although the more intense illuminants are not ignored.

Accompanying the pamphlet we have received some photo-micrographs of *Amphipleura pellucida* over four inches in length, which show that Mr. Bousfield flies at high game. These, he informs us, were taken by the new apochromatic objectives, with, of course, their accompanying eye-pieces.

THE AMATEUR'S FIRST HANDBOOK IN PHOTOGRAPHY.

By J. H. T. ELLERBECK.

London: Hamilton, Adams, & Co. Liverpool: D. H. Cussons & Co. Manchester: Heywood.

The present is a new and enlarged edition of Mr. Ellerbeck's manual. We have read it through carefully, and have nothing but praise to bestow upon the pamphlet as a useful and carefully written guide to those who want a reliable first handbook.

HOW TO BE A SUCCESSFUL PHOTOGRAPHER.

By W. J. LANCASTER.

Birmingham: J. Lancaster & Son.

In the fewest words compatible with lucidity in directions Mr. Lancaster, after giving a description of the various classes of apparatus desirable or necessary (profusely illustrated), takes the student by the hand, as it were, and having conducted him to the dark room proceeds to make up the various solutions required in order to produce a negative. He then touches upon the subject of portraiture, both in the garden and in the house, and having shown his pupil how to take and develop them, and to guard against the

pitfalls which lie in the way of the beginner, gradually leads him on to instantaneous work, in connection with which the tricycle and bicycle are impressed into his service. The production of magic lantern pictures and transparencies also finds a place in his manual.

VARIOUS CATALOGUES.

Mawson & Swan, Newcastle, and 33, Soho-square, London.

THE first of a series of catalogues emanating from this firm which we take up is that appertaining to *Chemical Apparatus and Chemicals*. It is a somewhat ponderous one of 132 pages, copiously illustrated from beginning to end. Although many of our readers only know this eminent firm in connection with photographic appliances, yet will a perusal of this goodly catalogue quickly apprise them that they are not only dealers in and manufacturers of chemical instruments and chemicals of all sorts, but are so on a most extensive scale. A perusal of this noble catalogue is truly fraught with suggestion.

The next in the list of Mawson & Swan's catalogues is that of *Electric, Magnetic, and Physical Apparatus*. Like the former this is a compendium in itself, the subjects being those appertaining to electricity and its cognates. It is *en suite* with the other, and is pagged to bind up along with it and those which are to be forthcoming subsequently.

Microscopes and Microscopic Apparatus form the theme of another part of this series, and in this, in addition to microscope stands and objectives, we have appliances for collecting, mounting, and storing objects, together with the cabinets in which these are to be ultimately kept for ready reference.

Department for Inexperienced Photographers.

THE USE OF A SWING BACK TO THE CAMERA.

THERE are three uses which may be made of a swing back, and these we shall treat in turn.

To explain its application to architecture, let us suppose that a photographer plants his camera in front of a large building. On looking on the ground-glass, he finds that though the building is square, and otherwise unobjectionable, its upper portion has not been admitted on the ground-glass at all. He naturally will raise the lens as far as the sliding front of the camera will admit of its being done, but this proving insufficient to get in all the upper portion of the building properly, only one course remains, namely, to point the camera upwards till the desired end has been attained. By this means the whole of the edifice is now got on the plate. But it will be found that, as a consequence of this tilting up of the camera, the sides of the building, which previous to the tilting were vertical, are now seen to be converging like a V inverted. In short, the building is distorted, the defect being designated as the *Distortion of Convergence*.

How is this to be remedied? We reply—By allowing the camera to remain undisturbed, but by means of the swinging back bringing the ground-glass in a strictly vertical position, so that, in fact, it is once more brought into parallelism with the vertical plane of the building. All distortion has now disappeared.

A convenient way by which the back can be rendered vertical, after the camera has once been placed, is to have a bit of thread with a small weight at the end, which when hung at the edge of the ground-glass acts as a plummet, and permits of the back being brought into correct position with speed and accuracy.

But seeing the plate is now standing obliquely to the axis of the lens, the upper part being nearer the lens than the lower portion, it follows that both top and bottom cannot be equally sharp in focus at the same time. This is most readily noticed when a large aperture is applied; but by inserting a small diaphragm the discrepancy is obviated, and all parts are practically made alike sharp. This distortion of convergence is more likely to be noticeable when lenses of wide angle are employed, and, therefore, when using such instruments exceptional care is necessary.

The swing back is also useful, and frequently necessary, in pure landscape work. All good landscapes should, if at all possible, have some salient objects in the foreground, which may consist of shrubs, flowers, stones, grass, weeds, or any of the innumerable objects to be found in nature.

When the view is focussed, and everything harmoniously arranged on the ground-glass, it will be found that the foreground objects, which if well selected should impart such a charm to a picture, are hazy from being more or less out of focus.

This arises from their vicinity to the lens, contrasted with the greater distance at which the other features of the landscape are situated, and by the law of conjugate foci, of which we spoke in the antecedent chapter

of this series of articles, both cannot be equally sharp on a plane at right angles to the axis of the lens. Therefore, in order that the foreground objects shall be brought into perfect sharpness without interfering with that of the distance, it is requisite that the ground-glass shall be swung back, in quite the opposite direction to that which was necessary in the case of architecture. The top of the ground-glass, on which the shrubs in the foreground are delineated, is now further from the lens than the bottom, the result being that both the foreground and the distance are alike sharp.

It is true that by employing an exceedingly small diaphragm the same end would be attained, but to do so the aperture would be unnecessarily reduced, which would be fatal to quick exposures.

The longer the focus of the lens that is employed in landscape work the more necessary that a swinging provision is made for securing the utmost sharpness of the foreground.

A third use of a swing back is when a portrait lens of large dimensions is employed in the production of a portrait of a sitting figure, especially when the camera is at no great distance from the sitter. The hands, if resting on the knees, together with the knees themselves, are under such circumstances not quite so sharply defined as the face, necessitating a slight swinging of the back to bring them into equality as regards sharpness.

Incidentally we may remark that when copying an architectural picture that has been distorted by the convergence of the perpendiculars, these may be rendered quite rectilinear in the copy by swinging the back, and thus introducing enough distortion of an opposite character to counterbalance that of the distorted photograph which is being copied. The result, as we have hinted, is perfect rectilinearity in the copy thus obtained from a distorted original.

No. 7549.—"Improvement in Metallic Easel or Stand for Photographs, Cards, and other like Articles." J. DEAKIN.—*Dated May 25, 1887.*

No. 7737.—"An Improved Method and Apparatus for Photographic Printing." J. HARRINGTON.—*Dated May 27, 1887.*

PATENTS COMPLETED.

IMPROVEMENTS IN FRAMES FOR DISPLAYING PHOTOGRAPHS, ADVERTISEMENTS, AND THE LIKE.

No. 13,783. WILLIAM MOFFATT, Millfield-terrace, Hexham, Northumberland, and WALTER SCOTT, Wanlockhead, Lanarkshire.—*October 27, 1886.*

THE improved frame under our invention is designed for displaying in rotation a series of photographic views or portraits, advertisements, and the like, and it consists of an ordinary portable picture frame or stand supported in an inclined position by a hinged or other bracket, and having suspended within it a box containing the series of photographs or other announcements, said box being capable of rotation upon a horizontal axis, and when in its normal position of rest replacing the "picture," which is ordinarily held stationary in the frame. The upper and under sides of the box have each two or more openings formed in them, through which openings the views to be displayed are seen and the views themselves are fitted in "slides" or shifting frames, which are placed in the box in two tiers, one tier loosely filling the box to the extent of half its length and the second tier partially filling the remaining half length or division of the box, a space equal to the depth of one of the slides being left by using an odd number of slides, so that the slide which for the time being is uppermost may be shifted from one end of the box to the other. The slides or shifting frames each contain two views or announcements placed back to back, so that in whatever position and order the slides may be placed in the box there are two views displayed at one side of the box and another two on the opposite side. In order to display in rotation the different views or announcements contained in the slides, the box is rotated intermittently by the use of a hand crank or otherwise, and it is brought to rest with one side in the same plane as the front of the supporting frame or stand by means of flattened discs, ratchets, or similar devices formed on a spindle, by which the box is suspended from bearing brackets on the back of the frame. On each movement of the box through half a revolution, the slide which is at the lower end of the box, and is on the top of the highest tier when the box assumes a horizontal position, is shifted or falls by its own weight to the opposite end as the box is turned over, and while by this movement it covers one of the views previously displayed it uncovers a slide containing a fresh view. When the box is again turned a like shifting of one slide from one tier to the other takes place, and by continuous turning of the box the whole of the views are in rotation shown at the front of the frame.

THE London Stereoscopic Company purpose holding their Third Annual International Amateur Photographic Exhibition in October next, when a sum of £50 in cash and a number of gold, silver, and bronze medals will be offered as prizes. The whole of the entrance fees will be given in full to the Photographers' Benevolent Association. All particulars relating to the Exhibition can be obtained by application to the Company's Secretary, 103 and 110, Regent-street, London, W.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.

" 8	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
" 9	Birkenhead	Free Public Library, Hamilton-st.
" 9	Bradford Amateur	Grammar School.
" 9	London and Provincial	Mason's Hall, Basinghall-street.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At a meeting of the above Association, held at the Masons Hall Tavern, City, London, on Thursday night, May 26, Mr. Herbert Starnes presided.

Mr. F. W. COX exhibited prints upon Fry's bromide paper; he said that they differed in type from those upon Eastman's paper.

Mr. A. MACKIE remarked that Eastman's paper was best for thin negatives. Mr. W. H. PRESTWICH exhibited some views taken by Professor Stebbing, of Paris.

Mr. L. MEDLAND exhibited a shutter invented by Newman, which he considered to be about the most perfect obtainable; it was one which gave the power of regulating the length of the exposures.

Two members exhibited some not very successful views of the Derby.

Mr. C. Heinrich Trinks exhibited a Beck's lens with iris diaphragm.

Mr. J. J. BRUGNSHAW asked the nature of halation and how it could be cured.

Mr. COX responded that for the most part it is an optical effect.

Mr. W. M. ASHMAN stated that Mr. F. W. Edwards had said that it could be cured by coating the ground side of ground-glass with the sensitive emulsion.

Mr. W. E. DEBENHAM was surprised to hear that statement, because the indices of refraction of gelatine and of ground-glass are so nearly alike.

Mr. A. COWAN remarked that halation is most prominent in under-exposed pictures forced in development, all other conditions being equal.

The CHAIRMAN asked if any one present knew anything about an alleged discovery by Mr. Mayall of a process for photographing in natural colours.

The HON. SECRETARY thought that Mr. Woodbury had once professed to do something of the kind.

Mr. DEBENHAM: Never. Hitherto Frenchmen only have introduced coloured photographs as photographs in natural colours.

Mr. COWAN thought, from what he could gather from newspaper reports, that coloured photographs would be the proper name for Mr. Mayall's new productions.

Mr. J. B. B. WELLINGTON read from *Nature* a paragraph about what he called "real" experiments on photography in natural colours by Mr. Carey Lea. That paragraph was printed in these pages last week.

Mr. W. H. HARRISON said that in early days photography in natural colours had been brought to a fair degree of perfection by Niépce de St. Victor, Becquerel, and others. At the first International Exhibition in Hyde Park about 1851, were some photographs of the spectrum taken by Niépce upon silver plates, and which were exhibited in subdued light. Mr. Warren De la Rue purchased one, and about fifteen years later exhibited it to him (Mr. Harrison) at Cranford. It was kept in a leather case, and was only opened occasionally in subdued light for the inspection of the curious, the difficulty being to thoroughly fix this class of photographs. A few months ago, when Mr. De la Rue was at Hamburg, he, in the course of some correspondence, asked him as to the condition of Niépce's photograph of the spectrum, and was informed that it is still in as good condition as ever. It is a very fair photograph of the colours of the spectrum, taken upon a silver plate chlorised by means of an electrical current while the plate was immersed in a bath containing various chlorides. If Niépce were allowed to dress a doll in what colours he pleased he could somewhat faithfully reproduce its colours in the camera image. Metallic objects came out with metallic lustre by this process; thus gold would look like metallic gold in the photograph, and not merely a yellow colour. Mr. Traill Taylor had informed him that Niépce fixed such photographs to a greater extent than many persons imagined.

Mr. TRINKS remarked that Niépce had found dextrine useful when producing photographs in natural colours.

Mr. MEDLAND asked if any one had seen a remarkable photograph by Van der Weyde at the American Exhibition of Mary Anderson, which stood out in such relief that many persons believed it to be a statue.

Mr. WELLINGTON stated that it was in a semi-dark room, spectators were not allowed to go near it, and were considerably limited in the selection of their point of view; it was inspected direct, and not through any optical device. A friend of his still believed it to be a statue.

Mr. COX suggested that an opera-glass would be useful in the inspection thereof.

Mr. TRINKS asked what was the greatest speed of shutter most generally useful for practical purposes.

Mr. DEBENHAM with a lens at $\frac{1}{2}$ aperture had given one-thirty-fifth of a second exposure from beginning to end of the opening of the shutter, equal to one-seventieth of a second of the full aperture of the shutter. These measurements had been made for him by his friend Mr. Haddon.

Mr. TRINKS remarked that it was impossible for the human eye to detect any movement more rapid than one-sixtieth part of a second.

Mr. DEBENHAM said that a flash of lightning passed in infinitely less than one-sixtieth of a second, yet could be seen by the eye.

Mr. WELLINGTON added that the eye could detect both the beginning and the end of the flash.

Mr. HARRISON was doubtful whether the shape of the flash did not convey the idea of the beginning and the end, rather than the actual motion.

Mr. A. L. HENDERSON had calculated, but was not sure, that when at a Derby race the horses were moving at the rate of sixty-five feet per second, the exposure he gave to take them as sharply as in the result could not have been more than one-two-hundred-and-fiftieth of a second.

Mr. DEBENHAM said that, accepting that estimate, if one-sixtieth of a second exposure had been given the horses would have moved slightly more than one foot, and that would have destroyed definition; the eye being fixed on the horses, and not on the background, might not notice the motion made in one-sixtieth of a second.

Mr. TRINKS, accepting Mr. Henderson's figures as to the length of the course and the time of the race, found by calculation that the speed of the horses was 49.55 feet exactly per second.

A question in the box asked if dextrine were good for mounting prints.

Mr. HENDERSON replied that it was not.

Mr. COWAN stated that it was too hygroscopic.

Mr. ASHMAN possessed prints mounted twenty years ago with dextrine and still as good as ever.

The meeting then resolved itself into a committee for the business affairs of the Association.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

At the meeting of this Society, held at the Greyhound Hotel, Dulwich, on Wednesday evening, May 25, Mr. A. Rider in the chair, Mr. MARSH read a paper on *Amateur Plate Making*.

Mr. Marsh went through the performance of the details of making an imaginary emulsion, using only a few ordinary household utensils for the work. The various stages of the process were accompanied with lucid directions and explanations. Mr. Marsh stated that a good emulsion can be made at an approximate cost of one penny per ounce, which quantity will coat six quarter-plates or one 10×8. Mr. Marsh also described the making of an emulsion by the ammonio-nitrate method, by which the trouble of washing is avoided. This process is so simple and cleanly that it may be performed in a sitting room. Some negatives were handed round which contained about a grain of silver in the film of each.

A cordial vote of thanks was given to Mr. Marsh for his highly interesting and instructive demonstration.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Thursday, the 26th ultimo, at the Royal Institution.—The President, Mr. George H. Rutter, in the chair.

The minutes of the preceding meeting were read and confirmed.

Mr. Charles A. Colman was unanimously elected a member of the Association.

The SECRETARY acknowledged the receipt from Mr. Cussons of a copy of the new edition of Mr. Ellerbeck's *Handbook on Photography*, also the photographic journals from the respective editors, and circulars of Pumphrey's glass-mounted films.

It was unanimously resolved that the recommendation of the Council, "That the Association do not think it expedient this year to join in the associated *sotée* arrangements," be adopted. A resolution was then moved and carried that the Association shall make arrangements for an exhibition and *sotée* of its own, and a committee consisting of Messrs. H. N. Atkins, Beer, Crowe, Lange, Mayne, Rutter, and Sayce, was appointed to draft a scheme for that purpose.

In the absence of Mr. Evans, Mr. RUTTER read a report of the excursion to Chester on May 7, from which it appeared that twelve members and two friends took part, that one hundred and nine exposures were made, fifty-nine on plates, forty-two on paper, and eight on Pumphrey's films.

Mr. RUTTER also, in Mr. Beer's absence, reported that on May 18 a full day excursion took place to Sandbach and Moreton. Eleven members were present, and one hundred and twenty plates were exposed. They went to Sandbach, thence to Moreton Old Hall, a very fine old timbered house, worth a whole day spent upon it, and returned to Sandbach. Dr. Kenyon exhibited a number of very fine enlargements on Eastman's bromide paper from quarter-plate negatives taken on Eastman's stripping films during this excursion.

Mr. EARR read a short account of the excursion to Worsley and Wardley Halls on Saturday, May 21, when they photographed Drywood Hall, the old landing place on the canal, Worsley Court House, Church, and Old and New Worsley Hall, only six members taking part in the trip.

The discussion on *Detective Cameras* was then opened by Mr. PAUL LANGE, who exhibited and explained one of his own construction, in the shape of an innocent-looking brown paper parcel, containing quarter-plate camera, Ross' rapid symmetrical lens, Eastman's roller slide, with Roger's indicator and Kershaw shutter, thus forming a very complete instrument; also some specimens of very fine work done by its aid.

Mr. Driffild, of Widnes, showed his modification of Marion's Academy camera, consisting of the addition of a focussing mirror. The camera works plates two inches square, and some fine enlargements were shown from these plates.

Messrs. Swinden, Kerry, and Comber, also exhibited detective cameras showing slight variations, but generally on the principle of the brown paper parcel.

Dr. Kenyon, and Messrs. Sayce, Tomkinson, Kerry, and Driffild, exhibited a considerable number of prints and other work.

Mr. Mayne exhibited Anderson's metal developing dish with attachment for lifting the plate out of solution; also Shew's folding rack for drying negatives, which shuts up into a very portable form.

A vote of thanks was passed to Mr. Driffild for coming over from Widnes to show his camera, and to the other exhibitors.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

At the meeting of the Society held on the 4th ultimo, Vice-President Bullock in the chair, Mr. BROWN announced the death of Mr. James E. McClees, an old Philadelphia photographer, who was one of the pioneers in the art in Phila-

delphia, and was well and most favourably known to the older members. Mr. ELLIS and Mr. BELL also added tributes of respect to his memory, alluding to the freedom of access to his laboratory formerly enjoyed by amateurs, and the help he was always ready to give at a time when every new discovery was jealously guarded by most professional photographers.

The papers of the evening were by Mr. Rosengarten, on *Photographic Chemicals and their Technology*, and by Mr. Bartlett, on *Photographing by Gaslight* [see page 343].

Mr. Trask showed a series of seventeen cabinet photographs of prominent Philadelphia clergymen, also three composite photographs made from the series.

Mr. VAUX, alluding to statements which had been made that the so-called photographs of lightning flashes are in reality only pictures of the illuminated edges of clouds, showed a series of pictures he had made of sparks from an electrical machine. From one to twenty sparks were included in each negative, and their form was so precisely similar to those of lightning flashes that there could be no question that lightning pictures were what they claimed to be.

Mr. Walmsley showed one of Horsman's Eclipse outfits, which were sold for two dollars, including all apparatus and chemicals necessary to produce photographs. He also showed some blue prints made upon postal cards which were prepared and sold ready sensitised for the purpose.

Correspondence.

Correspondents should never write on both sides of the paper.

CAREY LEA.

To the Editors.

GENTLEMEN,—The concluding sentence of your short article headed *Photochloride of Silver* must, I think, be heartily echoed by the older readers of THE BRITISH JOURNAL OF PHOTOGRAPHY. It was with mixed feelings of delight and regret that I this morning saw your announcement of Mr. Lea's valued communication in the current issue of the JOURNAL—delight, that its pages are again enriched with an intensely interesting record of his able investigations; regret, that ill-health has been the cause of his long silence.

Can I not venture to say that Mr. Lea may count upon the hearty sympathy and sincere good wishes of many like myself, who, though they know him not personally, remember his past service to our art-science? for he is one of that honourable company of original investigators which has a direct claim upon our gratitude and esteem.

That it may please God to quite restore Mr. Lea's health and strength and give him "length of days" for further usefulness, is the sincere prayer of—Yours, &c.,

W. HANSON.

71, Great George-street, Leeds, May 27, 1887.

STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—As the above specially interesting branch of photography seems to be again "creeping to the front," I wish to call attention to a fact I do not recollect having seen stated, namely, that a distinctly stereoscopic effect can be obtained from two prints from the same negative. Properly mounted for the purpose, the result, while of course not equal to that obtained by prints from the two negatives, is a decided improvement on the single print.—I am, yours, &c.,

JOSEPH H. WOODWORTH.

Sydney Lodge, 89, Booterstown-avenue, Dublin, May 30, 1887.

[If properly mounted, a stereoscopic effect will be obtained as between the mount and the picture, but not as regards the relation of one part of the picture to another. But we have in our possession more than one "stereoscopic" picture bearing the name of a maker of repute in another part of the world, which are unmistakably produced from only a single negative; but there being no well marked object in the immediate foreground to serve as a foil to the distance, the trick is rarely discovered.—Eds.]

UNRELIABLE MEASURES.

To the Editors.

GENTLEMEN,—Allow me to point out a source of error, and sometimes complete failure, which is not generally suspected. Some weeks ago I broke the foot off my last sixty-minim measure, used for measuring concentrated solutions for developing, and at once bought another supply. Since the new measure came into use my negatives have been poor and thin, and have taken longer to develop. Of course I did as we are all inclined to do, attributed the fault to the only source of all our failures—the plate maker, but a few days ago something prompted me to compare the old graduated measure with the new, with astonishing results. I found that sixty minims, according to the new measure, only filled up to

forly-five in the old one; I had, therefore, been using my developer nearly one-third weaker than usual.

Both sizes of measures were bought from the same firm, who ought to have tested these frauds, and have saved themselves from supplying photographers with pitfalls which even experienced operators would scarcely suspect. If we cannot trust our weights and measures where are we? No wonder that different experimenters get different results from the same formula if they are liable to this enormous variation in their measures. And one cannot help suspecting that the same principle may run through everything, and that we cannot hope to even get two supplies of the same article alike.

With this I send one of the measures that you may test it with a correct one, if there is such a thing.—I am, yours, &c., H. P. R.

[On testing the measure sent by our esteemed correspondent, we find, on testing it by one of our own, that it is inaccurate to the extent of nearly twenty-five per cent. This is truly reprehensible.—Eds.]

PATENTED INVENTIONS.—A DETECTIVE CAMERA.

To the Editors.

GENTLEMEN,—By parcels post I send you the remains of a detective camera, the back of which seems to be identical in principle with that described in your last issue as patented by Mr. A. S. Newman. Like it, my back is a box with a spring at the back forcing the plate forward to the front, and provided with a cover with two slits, through one of which the plate when exposed is forced up into a light-tight bag, whence it is passed down through the second by the hand outside the bag to take its place at the back of the box behind the other plates. The plates were contained in carriers of ferrotype plate. The only difference even of detail seems to be that while Mr. Newman provides a special mechanism to raise the plates on withdrawing the sliding shutter, in my camera an unexposed plate is pushed by the spring into its place, and on closing the slide after exposure is forced by it up into the bag.

This camera was made in the spring of 1885, and was first used out of doors on the Whit Monday of that year, and of course was shown to many of my friends. That it was quite a practical success you will see by prints I enclose from negatives, one of which was taken on the Whit Monday in question and the other a few days after, and I have always intended to reconstruct it in a more workmanlike manner. Perhaps you will kindly verify this description and return the camera, to defray the postage of which stamps are enclosed.—I am, yours, &c.,

Hotspur-street, Tyneworth.

HENRY R. PROCTER.

[All quite right as per above description; but the making and using of the instrument, and even the showing of it to friends, may possibly not be considered publication in the sense of overturning a patent. Why, when an invention is made, cannot ingenious photographers send an account of their inventions to the journals, for such publication as will be recognised in a court of law?—Eds.]

MR. NELSON'S PHOTO-MICROGRAPHIC APPARATUS.

To the Editors.

GENTLEMEN,—Perhaps you will allow me, as one who has had some experience in photo-micrography, to make one or two remarks as to this matter.

In the first place, it may be taken for granted, I think, that the chief thing to aim at is to get a correct and perfect adjustment of the image on the camera screen. Many devices have been adopted for this purpose, but they chiefly resolve themselves into that of rotating the fine adjustment button by means of a long rod, to which the button is connected by a cord, or thread; Dr. Maddox waxes the thread—a very good plan, which gives it grip. When using high-power lenses from $\frac{1}{2}$ inch upwards a variation in the adjustment of the $\frac{1}{16}$ of an inch, and even much less, is distinctly perceptible to the eye. Granting that the lens used is a good one, giving a sharp and finely defined image, and that the illumination is everything that could be wished, and the arrangements perfect, I would ask, What is it all worth if the whole are put wrong by the use of a slide incapable of working to register? I have seen several of the new metal slides, in fact I have three of them before me while I write, and there are none of them I should ever think of using, or dare to use, in a photo-micrographic camera. They may do well enough for a landscape where the lens has a considerable depth of focus, but in a photo-micrographic camera where there is none, it simply destroys and puts to naught the whole of the previous delicate arrangements. They are not flat in the slides, and I doubt much if they can be made so; and yet Mr. Nelson used slides of this sort. It cannot be too strongly insisted on that there must be the most perfect register between the image on the screen and the exposed face of the slide. If it were possible to remove the screen from the frame and substitute the sensitive plate for it, photo-micrography would be made a much simpler affair than it now is.

There is another point which requires the most careful attention,

namely, the utmost possible rigidity of that portion of the camera into which the dark slide goes. One maker of repute constructs a very nice apparatus for photo-micrography, but the whole thing, although well and firmly constructed otherwise, is spoilt by the use of a camera which racks out behind, and that portion has no support on the baseboard of the apparatus. Delicate focussing arrangements are of no avail unless the back portion of the camera is perfectly rigid.

I have been tempted to make these remarks by a notice of Mr. Nelson's arrangements in yours of May 13, which I have just seen, in which it is stated that the "advantage of using an eye-piece is undoubted in the direction of convenience." And so it is. The camera is shorter, the whole apparatus is more compact, and much more under control in the manipulation, and the field of view given by the object glass is flatter. But there are disadvantages which more than counter-balance these. One is the diminished light, rendering very much longer exposures necessary; another, and the chief of all, is that so clearly pointed out by Professor Abbe in his paper in the February number of the *Royal Microscopical Society's Journal*, namely, the use of an eye-piece has the effect of separating more widely the chemical and visual foci of the objective. It is so difficult to get a good micrographic objective in which these are combined, or nearly so, that no one ought to do anything to still further widen the breach. I have never used an eye-piece for photo-micrography. I felt that the eye-piece did harm, why I did not know. Now we know, and know that we should eschew eye-pieces.

Photo-micrography is now coming rapidly to the front, both for the purpose of book illustration and in the examination of diseased specimens of pathological tissues, and anything which tends in the least degree to render the apparatus more convenient in the use cannot but be of value, and cannot be made too widely known. Even your own valued contributor, Mr. Pringle, has been bitten, and is, I hear, pursuing the subject.

I do not make the above remarks in any captious, fault-finding spirit. I only want to add my mite to help on the good work to which so many able men are devoting time and energy, without, in some cases, knowing the why and wherefore of certain things about the art.—I am, yours, &c., PROCELLA.

STORING NEGATIVES.

To the Editors.

GENTLEMEN,—On reading an article in the *JOURNAL* of a week back on the subject of storing negatives, I thought a method I have employed for mine, and which I find very successful, might perhaps be of use to some of your readers, especially the amateurs.

I made a plain wooden box, twenty-seven inches long, nine inches high, by seven inches wide, of which the inside measurement is $8 \times 6 \times 26$. Then, by placing each negative in a separate envelope, the box will hold comfortably 200 half-plate negatives placed in on end. The lid of the box should be about two inches deep inside, so that when the box is open the negatives stand above the level of the box, as this greatly facilitates taking them out. A further convenience is to divide the box into ten compartments, by means of thin pieces of wood, which prevents too many negatives from leaning against each other. All my envelopes are numbered, and as each compartment holds just twenty any one number can be selected without disturbing a single other negative. When the box is full it can easily be stacked away, as it takes up very little room, and can be shifted from place to place with ease.

Any amateur can make his own box, or can have it made for a small sum. Of course, it must be fairly strong, owing to the weight of the glass; half-inch deal will, however, be found quite strong enough.

The dimensions I have given you are so arranged as to leave a decent margin, as it is easier to move the negatives if they are not packed tightly. It may be that this idea has been suggested before, but if not, and you think it might be of service to some of your readers, kindly insert it in your pages. I should be very glad to give you any further information on the subject, if necessary. Should you decide to insert this, do not hesitate to condense it, if you think you can simplify it, as I have no doubt the space in your *JOURNAL* is fully occupied.—I am, yours, &c., JOHN GLADSTONE.

Kelton, Edgbaston, Birmingham, May 29, 1887.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—Once more, and only once, I ask your kindly indulgence. Successful extortion cannot be eminently satisfactory to any honourable profession. To say it is so would be a slander, against which I, for one, would strongly protest.

One thing to be learned from the letters on this subject which have appeared in your *JOURNAL* is, that minds thoroughly warped with the interests of self to the exclusion of the claims of others are incapable of judging what is morally right and what is morally wrong.

The healthy and honest utterances of Mr. Dutton, of Bath, in your last issue, I take, from experience among them, as the representative utterance of the great body of photographers.

Mr. Dutton's letter, and the letter which follows, may some day prove to contain the data from which the question at issue will be finally settled.

—I am, yours, &c.,

J. F.

Newcastle-upon-Tyne, May 28, 1887.

To the Editors.

GENTLEMEN,—We are now getting on with Sitter versus Negative. Mr. Dutton considers throughout this trial "all your correspondents appear to have missed the point." It's now thought the greedy photographer, having purchased his plates, may be fully entitled to own the glass, gelatine, and silver contained thereon. But "the point" stops at the "impression," and this is the private and absolute property of the sitter. Good. Supposing he or she desires to exercise the right to take away the said "impression," will Mr. J. Dutton say how it's to be done, keeping in mind the film and glass belong to the photographer?—I am, yours, &c.,

T. Coax.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Ross' 12×10 single view lens in exchange for an Optimus or other rapid rectilinear quarter-plate.—Address, DIXON, Photographer, Colne.

Will exchange photographer's cart for half-plate portrait lens or photographic sundries.—Address, A. TAYLOR, Photographer, 77, Fore-street, Ipswich.

Wanted, camera and lens, printing frames, and posing chair. Will give good exchange in backgrounds.—Address, J. DEAN, Brook House, Clough, Golcar, Huddersfield.

Wanted, a good enlarging lantern or night-light in exchange for photographic dark carriage in splendid condition. Photograph sent.—Address, J. WALKER, 48, Wellington-street, Woolwich.

I will exchange 10×8 studio camera, having swing back with three motions, equal to new, and Voigtlander's No. 7 portrait lens, for a 3n Dallmeyer's or Ross' lens, or 15×12 outdoor camera and lens by any good maker.—Address, MELVILLE, 105, Market-street, Manchester.

Wanted, 12×10 very light camera, twenty-six inches extension, rising front, swing back; also twenty-four-inch $\frac{1}{8}$ or $\frac{1}{10}$ single landscape lens, and ten-inch wide-angle symmetrical. Exchange for quarter-plate camera, six slides, leather case, Sciopticon lantern, three-and-a-half-inch condensers and lens, 12×10 glass bath and ebonite dipper, nineteen-inch porcelain print washer, 12×10 new strong tripod, and Cadet's two-guinea shutter, working inside camera.—Address, PACO, 10, Cambridge-gardens, Richmond, Surrey.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under the three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

John Stuart, 120, Buchanan-street, Glasgow.—Two photographs of Rev. J. McGregor.

D. D.—We shall make inquiry and let you know (if possible) next week.

T. A.—Negatives that have been intensified after fixing should not again be treated with the fixing bath.

G. F.—First ascertain the focus of the lens, then determine the relations existing between the aperture in the stop and the focus; lastly, square these relations and compare with each other.

W. L. (Bridgwater).—We doubt not that the article advertised quite bears out what you say, but we like to see and test such things before admitting any certificate as to their merits. You labour also under the disadvantage of withholding your name.

J. HUMPHREY writes: "Having a permit from the Board of Works to photograph in Royal parks and gardens, can you kindly inform me if this permit includes Kew Gardens, Richmond, Greenwich, Bushy, Windsor, and other parks outside the metropolitan area?"—Our correspondent will only be allowed to photograph in the places specified on the permit.

QUERY writes: "In purchasing a first-class photographic business, on what principle should the valuation of the good-will be made, and what is the usual method of estimating the value of the negatives? If you could answer above in your JOURNAL I should be obliged."—We are unable to answer this query properly, and shall feel obliged if any readers conversant with the transfer of businesses will give the information.

LEX.—No description of roll holders other than in our publication of specifications of Patents has appeared in the JOURNAL.

GEORGIUS "would be glad of an answer to the following queries: He intends sensitising his own paper. He will sensitise perhaps once a-month. Will the bath keep uninjured if not used? He will place it in the sunlight to purify it. Does this exhaust the silver?"—In reply: The silver solution will keep quite good for an unlimited period. The only matter that is thrown down by sunlight is an organic compound that it is desirous to get rid of. A tablespoonful of kaolin kept in the solution will answer better.

INQUIRER writes: "I. Can you tell me if crayons suitable for doing backgrounds, as recommended by you a short time back, can be bought? If so, where? If not, do you know any one who would undertake to make them? —2. Can you recommend any particular detective camera up to half plate?"—In reply: 1. The crayons cannot be bought, but colours suitable for making them can be obtained from any oilman. This, mixed with a little water and dextrine, and moulded into shape and afterwards dried, is all that is requisite.—2. From what we hear, it is likely that quite a number of detective cameras will be in the market very soon.

E. B. sends queries as follows: "1. If a person is limited to one pair of stereoscopic lenses, what would be the most useful length of focus for them?—2. If the lenses are placed opposite the centre of each half of an 8×5 plate, can they be used in that position for an ordinary stereoscopic plate, that is, 6½×3½?—3. Is the single combination of a rapid symmetrical lens as efficient for landscape work as a single landscape lens of the same focal length?"—We reply: 1. About five or six inches.—2. Yes, certainly. See our articles on this subject in the ALMANAC.—3. A portion of a compound of the rapid type makes an admirable single landscape lens, but it is necessary that such an adaptation be made as to have the stop placed at a somewhat greater distance from the lens than when it is employed as an elementary part of a compound objective.

EDINA writes: "I have had great bother with my silver baths, new as well as old, for the last month, with a white-like seum or fog which when rubbed with finger or piece of cotton wool rubs up white. The baths work one or two plates at intervals all right, but then go wrong again. I have tried all usual remedies without success. I may also mention that dark room forms camera; have also had samples of silver from more than one firm. Do you think fumes of gas and other chemicals affect plates when in holder exposing? I may also mention I use same collodion and developers as I have used for years. If you can assist me out of my difficulty and favour with an answer in your next issue you will greatly oblige."—If our correspondent is quite certain that the fogging does not arise from light, then must the cause be organic matter in the silver bath. Add a few drops of a weak solution of bicarbonate of soda—enough to render the bath slightly milky, expose in the sun for several hours, acidulate with nitric acid, filter, and employ a collodion that is of a sherry colour, and the fogging will be a thing of the past; but no gaseous fumes must be allowed to have access to the plates while being exposed. A few drops of tincture of iodine added to the collodion will frequently ensure cleanness of the image.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—On Saturday, June 4, there will be an excursion to Loughton. The train leaves Liverpool-street (Great Eastern Railway) at thirty-five minutes past two p.m.

HOW IT IS IN PARIS.—The following is an extract from a note received from Mr. Prithoe, of Bristol:—"I have just returned from Paris, and write to thank you for so kindly sending me an introduction to Professor Stebbing. My friend Mr. G. Scamell accompanied me over, and I lost no time in sending your note to Mr. Stebbing, who wrote me making an appointment, and I spent a most pleasant and profitable day in his company. He took us to see several first-rate studios—the most interesting being M. Nadar's, who received us with a hearty welcome and showed us around his fine establishment. Amongst other things he showed us some good work on Eastman stripping films—some he had just taken of the fire at the Opéra Comique. The weather was most unfavourable for outdoor work, but what we saw was very good under the circumstances. M. Nadar told us he never got any failures with the stripping process, and seemed to be greatly pleased with it. His reception room is a most elaborate place, and his sitters are conducted to his studio on top of the house by means of a lift. I noticed several good features at this place which I shall endeavour to benefit by. Mr. Stebbing could not have been more attentive and kind to an old friend than he was to us, and I shall always remember our pleasant day together. I was very sorry to see his nice little plate factory in ruins, and although fully insured he has a troublesome lawsuit pending with the insurance company, which I wish him well out of."

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1414. VOL. XXXIV.—JUNE 10, 1887.

THE LATEST THING IN PHOTOGRAPHY IN "NATURAL COLOURS."

THE old adage says that "It never rains but it pours." Scarcely has the Mayall process of (alleged) photography in natural colours had time to cool down by the discovery that it is *not* a process of photographing in "natural colours," than, as we hinted last week, another Richmond enters the field, this time the Cellierier Syndicate, Limited.

Although the title this Syndicate adopted at first—"Photography in Natural Colours"—was misleading, and therefore reprehensible, yet when we pointed out to them the real meaning of the phrase as long understood by scientific photographers, they at once disavowed any intention of desiring that the public should be deceived by any misleading term, and have lost no time in amending their title to the more accurate one of *Photographs in Colours*, to which no objection arises.

Responding to an invitation to see specimens of the Cellierier-Parkes process and to witness the method of producing them, we called at their gallery in Pall Mall, where we saw several examples of the work, but did not witness the operation of producing them, for which purpose we were told we should have to visit their works in Sidcup, Kent, where the pictures are made. The appearance of these prints is in some cases rather pretty, bearing a resemblance to good work executed by the time-honoured and times-without-number-patented crysolium process. One of the specimens having been dissected revealed the fact that it consisted merely of a transparency on glass, having a white paper backing, upon which had been painted washes of water colours which, when the transparency was superimposed, showed through and thus imparted apparent colour to the picture, the drawing, lights, and shadows of which were obtained in the course of ordinary photography. How, on the strength of such a process, the "invention" has been acquired, as we are told, by a party of influential British capitalists—the Cellierier Syndicate, Limited—we are unable to say, but it speaks well for the organising ability of some one.

We were, some months ago, shown a prospectus, when the shares were being issued, in which it was stated as an inducement for intending applicants that a large amount by way of returns would ensue from the royalties or licences paid by professional photographers all throughout the country, who, to save themselves from the successful competition of others, would be compelled to become licensees of the company; and our friends naturally will look to us for information as to how or to what extent they will incur danger to themselves by

either colouring a transparency from behind or backing a plain transparency with paper having on it washes of colour.

The first (or among the first) to apply a coloured paper backing to gelatine transparencies, which in those days were made by the Woodbury process, was R. H. Ashton, who, in March, 1866—now over twenty-one years ago—obtained a patent for an invention entitled "Improvements in pictures obtained upon paper, glass, porcelain, or other surfaces with transparent or semi-transparent materials." In this the backing paper was printed upon in flat tints by chromo-lithography, or "by any other known process." We feel rather an interest in the Ashton process, because we have still in our possession specimens of his backing papers (which he called chromotypes), and also because such chromotypes have, as we think, a not unimportant bearing upon the invention patented by M. Cellierier. Anyway, those of our readers—and they are not few—who have entered the field of photography within the last two decades will be glad to know what was done in this direction anterior to their time.

The Ashton process, the originator of which was in business alliance at the time with the late Walter B. Woodbury, consisted in backing a transparency with white paper, on which was depicted either by hand or (for large quantities of prints) by chromo-lithography, such a backing in colours as served to show behind the transparent photograph, and thus impart apparent colour to it. Much of Ashton's specification is devoted to the most convenient methods of obtaining correct registration when superimposing the print upon the chromotypic backing, but this is of no consequence for us just at present. What we are seeking to show is that the principle of backing transparencies with paper washed with colours had been long ago recognised. To establish this more clearly, we make a quotation from the specification: "I have above particularly alluded to obtaining prints on paper; when they are to be on glass, porcelain, or other hard substance, angle pieces may be adopted; the position of these angle pieces are transferred to the surface which effects the colour printing," &c. Again, "The two printings may be combined by transferring a print obtained in gelatine to the chromotype, in order to effect which the following method may be adopted." Here follow details. "After which the paper may be stripped, leaving the gelatine print superimposed on the chromotype." If the gelatine print be on glass, the registration is adjusted to the chromotype by hand. "I have hitherto supposed that the coloured picture" (the backing) "is produced by printing; but the same effect may be produced by filling in the required tints by hand, and

this method would of course be adopted when a few copies only were required."

Now it appears to us that the Ashton invention, of which we have here given only an outline, presents features of marked similarity to the new Cellier process. Be this as it may, our readers will, from the foregoing, judge to what extent they may go without infringing any patent, the one in question having lapsed many years ago.

Towards the end of the same year, 1866, the papers literally gushed over an alleged new process of photography in colours which was going to revolutionise the art. This is the way in which it was heralded by one of our daily papers:—"The honour of producing on paper the exact colouring which the human form throws on the camera has been reserved for M. Chambay, whose process I have carefully investigated, and am able to declare that he succeeds in producing a portrait which gives all the exquisitely varied tints of flesh, together with a transparency in the shades never before attained. This is a great chemical triumph." But it was quickly revealed that this revolutionary process, this "chemical triumph" consisted in superimposing a very transparent coloured picture over an opaque one more strongly tinted with brilliant colours. And after an inspection of some of the Chambay pictures we wrote at the time that the colours were not obtained, as alleged, by chemical means but were put on by the brush, and we added that the processes for producing such effects had, on several occasions, been published in the JOURNAL. And this was in December, 1866.

We have no desire to say anything here concerning the Cellier patent, or its validity, as we shall take an early opportunity of reprinting it in its entirety; but so far as we were permitted to see the result of the process (and we speak only of what we saw) their invention appears to have been in a large measure forestalled by those to whom we have referred, not to speak of the system so successfully adopted by the late Oliver Sarony in connection with his large portrait transparencies, which were backed with papers containing hatchings executed by lithography and also by tinted sheets.

EXPOSURE.

WHAT may be considered a correctly timed negative? This is a question impossible to answer, inasmuch as there is no real standard for comparison, and even if there were a great diversity of opinion would still exist amongst different operators. Supposing a batch of negatives of average quality were submitted to half a dozen photographers, various opinions would be expressed as to which out of the number had received the most correct exposure. If this diversity of opinion exists with reference to negatives when they are finished, what must be said with regard to the exposure in the first instance?

Every experienced photographer knows quite well there is such a latitude allowable that it is possible to produce fairly good, if not indeed very good, negatives when there has been a great departure from what may be termed the normal exposure, supposing such a thing to exist. This, as every one knows, is accomplished simply by modifying the development. This brings us to the point for present consideration. Given two photographers working on the same subject, with the same plates, and under precisely identical conditions, it will often happen that the one will habitually give a much longer exposure than the other, and yet each will obtain in the end equally

good negatives. This is owing to the development being conducted by the two men under different conditions—the normal developer employed by A. being in fact what B. would consider only suitable for what he would term under exposed plates, while that used by B. is just such as A. would think fit only for what he would designate over exposed ones. In a word, B. would look upon A.'s negative as being under exposed and forced in the development, while, on the contrary, A. would consider B.'s over exposed and restrained in the development. But, as we have said before, both operators may obtain, to all intents and purposes, equally as good printing negatives.

This diversity of opinion as regards the proper exposure has not arisen entirely since the introduction of dry plates, as it existed, though, perhaps, to a minor extent, in the days of wet collodion. It then often occurred that what one artist would consider a correctly timed negative another would pronounce over, or perhaps under, exposed. Some operators, as a rule, gave a much longer exposure than others and considered it absolutely necessary for the best results. With the maximum of exposure the details of the picture quickly appeared when the iron developer was applied. The plate was then intensified with pyro and silver to the requisite density. When, on the contrary, the minimum of exposure was given, the iron solution was more relied upon to bring out the image, with the result that it came out more slowly, and by the time the negative was fully developed little, if any, after intensification was necessary.

Here, again, equally as good printing negatives, apparently, were secured under, in some cases, widely different standards of exposure. The two classes of negatives obtained under these conditions we have heard familiarly described as "light negatives" and "chemical negatives," according as the power of the light of the developer—if we might use the term—had preponderated.

Now, however much opinions may differ amongst experienced artists as to the theoretically correct exposure, there is no question whatever that a very large proportion of amateurs' negatives are decidedly much under timed and more or less forced in the development. Of course we are not alluding to the work of the well skilled amongst amateurs, but more particularly to those of somewhat limited experience.

Generally, when looking through a collection of prints from amateurs' negatives, one can scarcely fail to be impressed with the general lack of detail in the deepest shadows, these being too frequently represented as little better than black masses. Particularly is this the case with foliage. In most cases an examination of the negatives will show that the detail may be all there, but of a very feeble character. Consequently, by the time the lights are printed through, the shadows have become completely buried and lost. The real test of the quality of a negative, it should be borne in mind, is not what can be actually seen on looking through it, but what it will yield when printed from.

It was one of the maxims in the collodion process, "Expose for the shadows and leave the lights to take care of themselves." This maxim should also be applied to dry plates. If it were, it would be found that many amateurs' negatives should have had twice, and, in some instances, as much as three times the exposure they received. Had this been the case, the shadows would have been full of detail, and the whole picture harmonious instead of being heavy and patchy. Knowing full well this general tendency towards under exposure with amateurs, we introduce the subject once more in

order that they may steer clear of the reproach which applies to so many of their productions. The novice ought to bear in mind that a good negative should possess no clear glass whatever, save in the *extreme* points of the deepest shadows, and even these may often be slightly veiled with advantage.

A FEW years back, when more interest was bestowed on the electric light in its commercial aspects than is being done at present, the late Sir William Siemens, at the conclusion of a course of lectures at the Society of Arts on the dynamo, its construction and capabilities, in proposing a vote of thanks to the lecturer remarked somewhat to the following effect:—He wished the public would attend such lectures as those just delivered, and learn something about the subject dealt with, instead of rushing off to the Stock Exchange with their money. This was sound and genuine advice, and applies equally as well to other speculations as to those on electric lighting.

WE learn of a very singular paper having been read at a recent meeting of the Canadian Institute by Dr. Rosebrugh on *Photography of the Interior of the Living Eye*. The feat was performed as follows:—A glass transparency was illuminated by the sun, and reflected into the eye by a piece of plate glass placed at an angle of forty-five degrees to the rays passing through the transparency. The image thrown on the retina was viewed through this glass from a point situated in the axis of the eye, and a small camera and lens there placed, which gave an image of the picture on the retina, and it is stated that photographs taken with about five seconds exposure by this means were exhibited at the meeting. Of course the pupil of the eye had first to be dilated by artificial means before making this very remarkable experiment, and it is obvious that, even with a five seconds' exposure only, the submitting of the eye to the strong illumination described, and the keeping it motionless for the time required, must have necessitated a considerable amount of painful endurance and steadiness of nerve.

OUR contemporary, the *English Mechanic*, recently printed a letter from a correspondent asking the meaning of the expression, "a ten per cent. solution," a form of words whose liability to misunderstanding we have before alluded to in these pages. It is, however, quite evident that, whatever practical skill and theoretical knowledge many amateurs and others are possessed of, the knowledge of the application of elementary science to tables of weights and measures is by no means general; for on reading the replies to this particular query we note that, though six correspondents have rushed to the rescue, one only—and he dismisses the subject in a few lines—has managed to escape blunders of a most egregious description. The subject is by no means an unimportant one, and we will, therefore, make a few practical observations upon it very shortly.

WE have on former occasions referred to the manufacture of sundry articles useful to photographers from paper, and we now learn that the production of paper bottles is become an important industry in Chicago. For photographers who are travelling about, such vessels would be of the greatest use, and we should imagine that they will ere long become part of the usual stock of the dealers. These bottles are coated internally with a protective varnish, which is stated to be capable of resisting both acids and spirits. The bottles are constructed by first making a tube by rolling upon a mandrel sheets of paper cemented upon one side, which tube is then cut into suitable lengths, and fitted with wooden or paper bottoms cemented in their place, and also, when required, with the paper necks, which likewise are cemented to the tube. All that is then necessary is to varnish the interior with a suitable material, which protects it in the efficient manner described.

WE have on a previous occasion referred to the photographing of a bullet during flight, a feat whose counterpart was performed a quarter of a century ago by Mr. Skaife, who, as some of our readers may remember, took a negative of a shell after leaving the cannon's mouth.

This later feat, however, possesses points of special interest. It does not need explaining that the rapidity of the flight of a projectile is nowadays far beyond that obtained at the period we speak of, though, again, this difference is more than discounted by the sensitiveness of dry plates as against wet collodion. The projectile in the present case was fired from a Werendler gun, its velocity being thirteen hundred feet per second. The negative gives an image not only of the projectile itself, but also of the layer of air enveloping it, which is seen to be of a hyperbolic form.

THE marvels of modern photographic representations are by no means exhausted by the above recorded examples. Mr. Baker, the architect of that wonderful piece of engineering skill now so near completion—the Firth of Forth Bridge, gave a most interesting account of the work and its progress in a lecture delivered at the Royal Institution last month. During the course of his lecture he stated that photographs had been taken of the interiors of the huge caissons, which, diving-bell wise, were used to work from at the bottom of the water. These caissons were entered through an air-lock, and the pressure of air was often as high as thirty-five pounds to the inch. The photographs, however, were defective from a singular cause: every one who has experimented with an air-pump has noticed the haze produced when the pressure of air is first reduced, and a similar effect was produced in these caissons. Every now and then the compressed air would find its way out of the huge chamber, at the edge, and then a haze was formed resembling the air-pump mist, which naturally affected the integrity of the shadows of the photograph. This it would be the more likely to do, seeing that the glare from lamps of an aggregate power of six thousand candles would heighten the effect. Mr. Baker says exposures of fifteen minutes were sometimes given, but "the results were not so good as could be wished, the eyes especially coming out in a glaring, spectral fashion." With exposures of a quarter of an hour, and the barometer standing at about seventy inches, it could scarcely be expected that niceties of expression could be secured.

It is little probable that light modification for dark room purposes will ever be brought about by other means than the familiar one of filtration by means of coloured screens of translucent material—glass, paper, or woven fabric. It is, however, when delicate experiments are in question, well to remember that no one screen used is absolute in its light separating power, as some of the more refrangible rays will pass through almost every substance in popular use for the purpose. It is useful, therefore, to have in our power still other means for producing monochromatic light, and these would seem to be available in a method recently described in a foreign journal. The expedient is simple. A salt which is known to impart a certain desired colour to flame is put into a hydrogen generating apparatus at the same time as the zinc, and the gas required to feed the flame is then passed through this flask on its way to the burner. It must be said of this method that gas so passed should be hydrogen, for if ordinary coal gas were used we should anticipate the actinic rays usually given out from its flame to be simply masked and not intercepted or destroyed.

HARDWICH ON THE OPTICAL LANTERN.

I THANK you for the bundle of JOURNALS you sent me containing articles on lantern matters. I have read them with much pleasure, and with your permission should like to make a few remarks.

First, as regards Mr. Brooks's paper on the oxyether or "ethoxo" light. I am one of those who think that Mr. W. Broughton, of Manchester, has been badly treated. He gave us a simple and reliable process, and has received but a scant measure of praise. They say that the oxyether is not safe in the hands of inexperienced persons who decline to follow instructions; but may not the same be said of the oxyhydrogen? and yet this process is much used.

Mr. Brooks speaks of the ether throwing down a white deposit on standing. This, I think, must be due to the materials used in soldering the tank, as I have never observed anything of the kind in my own experience. The methylated ether I employ is supplied to me as a favour by Messrs. Mawson & Swan, of Newcastle-on-Tyne, and is, I

fancy, the same they use for their collodion. It is so light that a 1000 grain s.g. bottle of it weighs not more than 710 grains at 60° Fahr., and I use it over and over again by filling up to the original bulk with fresh ether. It would be no advantage to use cheap and inferior ether of 750 or more, as greater attention would have to be given to the taps, from the constantly decreasing volatility of the fluid.

During the past season I have used the oxyether limelight almost exclusively, with the modified form of tank and safety jet described in your JOURNAL about a year since. No difficulties of any kind have occurred, with the exception of an occasional hissing or roaring noise when the bag is heavily weighted.

Any one who has not heard this unpleasant noise may produce it, at will, in the following way. Begin by selecting a nipple which experience has proved to work silently at high pressure, and remove lime dust or any other kind of roughness by polishing the interior of the bore with a needle of a suitable size, scratched transversely by rotating it on emery powder between the finger and thumb, as advised by Mr. Lewis Wright. Then get all into working order, and whilst the flame is playing quietly against the face of the lime, with the two gases in the right proportions, *pinch* the shut piece of rubber tubing which conveys the oxygen from the tank to the jet until the channel is almost obliterated; the flame will rise to a great height in the lantern, but there will be no noise. Now release the oxygen tube and pinch the ether vapour tube in the same way; the flame will then become small and blue, and there will be a loud roaring or hissing, which can be heard at the further end of the lecture room. Even when you remove your finger and both gases are flowing again in the correct proportions, the roaring will continue, but if you lift the lime cylinder off the pin and take it quite away it will cease. Evidently, therefore, the lime has something to do with the hissing, and so has an *excess of oxygen* in the flame. High pressure must also be taken into account, and this is the reason why the roaring often happens at the beginning of the lecture, because the sides of the bag are then tight, and every pound of additional weight tells. Also because the air has not been entirely expelled from the tubes, for I find that oxygen contaminated with atmospheric air is more noisy than pure oxygen.

To prevent the hissing, load the bag at first with not more than two half-hundredweights, and if it is a large bag, eight feet or more, put on another fifty-six pounds at the end of twenty minutes or half an hour, always taking care to see that the edges of the flame are red from excess of ether. If the noise should begin in spite of this precaution, turn off the O tap until it ceases, and then gradually turn it on again to the right point. When the bag is half empty, we may put on a fourth fifty-six pounds; but I find no advantage myself from doing so, provided the granule chamber be kept in working order by an occasional pricking out of the wire gauze with a needle and filling up with fresh pumice.

No "snaps" or "passing back" must be permitted, or the wire gauze will soon be choked up, and heavier weight be required on the bag. Extinguish the flame at the end of the lecture by turning off the H tap slowly and allowing the O to blow it out. In the case of dissolving lanterns keep the bye-pass rather high, and if snapping still occurs file the H groove in the plug of the dissolver a *little* longer and deeper than the O groove.

I have now said enough on the precautions to be taken for securing a noiseless flame; only one more needs to be mentioned. Notice the distance of the lime cylinder from the jet, as the hissing is worse when it is too near. Supposing the nozzle to be bent at an angle of 45°, a quarter of an inch will be a suitable distance, measured in the direction of the flame. But as the limes I use are all exactly of one size, I find it answers very well to measure *half an inch* from the orifice of the jet straight across to the lime pin, and the flame will then be exactly a quarter inch long before it strikes the cylinder. You may see when it is right by the appearance of the lime itself after use; it should be worn away into a shallow cavity of an oval shape, and if it is drilled with a number of circular holes side by side the cylinder was too near.

Mr. Brooks is quite right in saying that the two short lengths of rubber tubing which connect the tank with the jet should not be allowed to get out of condition. This, in fact, is the principal element

of danger in the process, and I once heard of a case of that kind which nearly led to a disaster. A bottle of compressed gas was turned on rather suddenly, when the rubber ripped up from end to end, and a flame shot out a yard long. Even supposing the tube to stand, it might easily be forced off from its connection with the jet, and a stream of ether, more or less explosive from admixture with oxygen in uncertain quantity, be lighted from the nearest flame. I am glad to be assured by Mr. Baker that with the "automatic gas regulator" nothing of this kind could happen; but I think it would be an improvement if Mr. R. Beard, the inventor of the valve, could make it equivalent to *six inches* of water pressure, when desired, instead of twelve inches. Meantime, we must secure ourselves by tying the rubber carefully to the jet, and choosing a strong kind, in which the diameter of the two sides together is as great as that of the bore (half inch tubing, with sides of one eighth inch thick and a quarter inch bore).

Zirconia Light.—This paper, by Mr. Lewis Wright, interested me extremely, and strengthened the conviction I had previously formed that the brightness of the limelight disc on the screen depends on the *area* of ignition as well as on the intensity. It seems that Zirconia is not a good conductor, and that the incandescence does not spread. I have noticed in the limes of different makers that some give a larger area of ignition than others, and more light; also a difference in the colour of the illuminated disc, which is *yellowish* with one lime cylinder and pure white with another. The oxyether flame is larger than that of oxyhydrogen, and hence, although its heating power is less, the ultimate result, as regards brightness of disc, is nearly the same. We can see at once by looking at the lime cylinder that a much larger surface is incandescent when ether is used in place of coal gas.

The above remarks do not apply to the limelight used with the microscope. The radiant ought, I presume, in that case to approach more nearly to a point.

Dissolving View Apparatus.—I can never regret having purchased a binial lantern, because I have learnt much by it that I could not have known in any other way. Nevertheless, I find that, as years go on, I use it less frequently than I once did. My people seem abundantly satisfied with a single lantern, provided it is a good one, and the lecturer, when left without an assistant, has less upon his mind. I agree with Mr. A. W. Scott that the pictures are not intended to supersede the lecture, but to illustrate it, and therefore the less of reading from a book, and the more of a simple and natural talking to the audience in your own words, the better.

A friend came to me not long since prepared to spend sixty pounds upon a triple lantern, but I advised him not to do so at that time. It would, I thought, be better for him to perfect himself in the first instance with a single lantern, and then to consider what should be his next step. It often happens with these double and triple lanterns that the condensers are not exactly of the same size, nor the grooves in the slide carriers of equal depth. Hence an amount of adjusting and centering is required most puzzling to a beginner. The management of the limelight is also more difficult than in the case of a single lantern.

Manufacture of Oxygen.—A student fresh from the chemical laboratory has been accustomed to make small quantities of oxygen gas in a glass retort, and has been taught that the presence of oxide of manganese facilitates the escape of the O from heated chlorate of potash. He therefore naturally concludes that the more he uses of this black powder the quicker will be the flow of the gas. In preparing large quantities of oxygen, however, for the limelight, he finds that a sixth or an eighth of manganese enables him to fill his bag more quickly and at a lower temperature than when he adds one-half. There is, no doubt, some danger of a "rush," and therefore the tubes must be kept well open from end to end. I myself work in this way because time is an object, and the iron retorts last longer when they are never allowed to get red hot, but I think Mr. Lewis Wright's advice is better for beginners, namely, to proceed cautiously at first, and to use the maximum quantity of black oxide. I am surprised, however, to hear him say that he finds the powdered chlorate to yield less oxygen than the crystals. With me it is quite the other way, and by looking at his figures I see that I get more gas per pound than he does. Perhaps the powdered chlorate he uses has been kept for a time, and has undergone some decomposition in consequence.

I do not recommend an impure sample of chlorate. If retail dealers

would once try the chlorate of potash manufactured wholesale by Messrs. Kuntz & Co., of the Sutton Alkali Works, St. Helen's, Lancashire, they would, I think, be astonished to find that so good an article could be made by one crystallisation, and at a moderate price.

For purifying the gas I employ two common zinc washers of the usual size ($5 \times 4\frac{1}{2}$), with a pint of solution of "washing soda" in each. The entrance tube of the second is closed at the end, and then drilled with half a dozen or more holes one-sixteenth of an inch diameter, like what is called a "rose burner." This prevents water from being driven into the pipes however fast the gas may come over, and the holes do not become choked, as the black powder is deposited in the first washer. Note, however, that *rain water* should not be used for dissolving the soda, as it often contains organic matter and causes *frothing* of the liquid.

I have not as yet had an opportunity of trying the addition of "salt" to the oxygen mixture, but hope shortly to do so.

T. FREDERICK HARDWICH.

GELATINE DIRECT POSITIVES.

HAVING undertaken, with a friend, to open a photographic studio in a bazaar for a charity, the question arose how to take a gross or so of quarter-plate portraits in the course of an afternoon, and as far as possible to hand them, finished and framed in trays with mats and preservers, to the sitters before leaving in the evening.

A direct positive process of some kind or other was at once decided upon as the only one sufficiently ready, and the following was the procedure adopted.

The plates (a cheap, thin make of instantaneous gelatino-bromide dry plate was selected) received a very short exposure (but not with a drop shutter). They were developed with ferrous oxalate, the development being stopped as soon as the detail was all out, but while the image was still bright on the surface and the shadows still unclouded. The alum bath and hypo bath were then used as usual, and after a moderate washing the image was bleached with iodine dissolved in solution of potassium iodide (colour of golden sherry). A dilute solution of ammonia after rinsing, or perhaps soaking in water, whitens the image and clears the film from excess of iodine. The plates were then dried and varnished with clear negative varnish, and backed in the frames with black velvet.

It is essential that the development be stopped long before the density suitable for a negative has been attained, otherwise the shadows would not be clear and show the backing well through. For the same reason the exposure should not be sufficient to cloud the shadows in the least.

The iodine solution should not be too strong, otherwise a considerable excess will penetrate into the film, and a prolonged soaking in water or ammonia solution be required, which may injure the result.

The plates *may* be varnished with black varnish, but unless they be much more strongly developed they will be too dark in colour.

The process may appear too obvious to be worth mentioning, but I have failed to find any convenient process for the utilisation of gelatine plates for direct positives in a textbook or periodical. We had not sufficient confidence in the permanence of an image bleached with bichloride of mercury to risk its employment, though the freedom of the yellowish, creamy colour of the silver iodide gives it at first a more pleasing effect, and Obernetter's process for direct positive images was too complicated, and did not fully succeed in our hands.

The process above described can hardly be surpassed in simplicity, and though, like all direct positive processes, it does not admit of ready multiplication, it possesses other advantages. For a framed landscape it affords rather a pleasing effect, and there may be cases where an amateur may require only one or two copies for framing, which may more easily be obtained directly in the camera than otherwise.

I have not tested it to ascertain whether with shorter exposure than is required for a negative the same details might be secured. If this be so, this, or some other direct positive process, might of value for astronomical subjects.

It should be noted that the iodine solution should be saturated with iodine, there should be no free potassium iodide, otherwise the strength of the image will be impaired.

ROSSE.

Athenæum Club, Pall Mall, S.W., June 8, 1887.

THE FOCUS OF LENSES.*

In catalogues one also meets with the term "back focus." This term is of no value whatever, and only represents the distance from the back of the lens to the focus. It is entirely unscientific, and could be neglected without loss to anybody.

The following explains a method often given for obtaining the focus of a combination. We stated above that as the distance between the lens and the object increased, the distance between the lens and the image decreased, and *vice versa*. This is always so, and changing the lens only changes the actual distances, which still remain proportional to each other. If, then, we could get an equation embodying these two distances, from object to the lens, which we will call A, and from the lens to the image, which we will call B, as known, for we can measure them, and the focal length F, as unknown, we could determine this latter. Now this equation is—

$$\frac{1}{B} - \frac{1}{A} = \frac{1}{F} \quad (1)$$

Now if A, the focal distance between the lens and the object, be of an infinite length, and $A = \infty$; $\frac{1}{A} = 0$, and then $\frac{1}{B} = \frac{1}{F}$, that is, the conjugate focus equals the principal focus. We reasoned this fact out in the beginning of this paper.

Equation (1) can be written

$$\frac{A \times B}{A + B} = F \quad (2)$$

and this, or some such form, is given in many books as a good method of obtaining the focal length.

What it practically comes to is, you place a candle or other object at some distance, which you guess to be more than twice the focal length of the lens; then focus it on the glass, measure the distance from the object to the centre of the lens, which can be taken as the diaphragm slot, and the distance from the slot to the ground-glass; then the product of these two distances, divided by their sum, gives the focal length.

For instance, we find the first distance to be 33", and the second 10; the $\frac{33 \times 10}{33 + 10} = \frac{330}{43} = 7''.7$, the focal length of the lens.

But we have been obliged to assume that the diaphragm slot is the optical centre of the combination. This is undoubtedly true in most lenses of the rectilinear type, but in triplet or portrait lenses, without central diaphragms, we must seek a fresh equation.

We remarked above that when you brought the object near to the lens the image receded from the lens. Now, if you continue such a movement, you must come to a position where $A = B$, or the two conjugate focal lengths are equal and equidistant from the lens.

In such a case equation (2) becomes

$$\frac{A}{2} = F \quad (3)$$

that is half the distance from the lens to the image or object, or one-quarter the total distance between the object and the image gives the focal length. Practically you shift the camera and alter the focus till you get the image of the same linear dimensions as the object, for it is a property of lenses that when their focal lengths are equal, the images they form are also equal. This method is very largely used, and has been repeatedly advocated. It possesses but one fault, equation (1), on which it is based, does not take into account the thickness of the lenses themselves, and in cases of short focus lenses, where the thickness is naturally considerable in respect to their focal length, the error may become appreciable. We must, therefore, seek some other method free from this fault.

Now, the result of any lens or series of lenses is, after all, only to alter the angle that the object subtends. This is equivalent to saying that it alters the size, and this size is directly proportional to the focal length. Now, then, if we have a lens of a known focal length F, and we focus some object on the screen, and measure its size Q on the screen, then, with our unknown lens X in the same position, focus the same object on the screen and measure it, P

$$\text{then } Q : P = F : X \quad (4)$$

In practice, if with our known lens of 6" focus, the image Q measures 3", and with our unknown lens the image P = 4", then

$$X = 6'' \times \frac{4}{3} = 8''$$

And this is correct if the objects are distant enough to be considered as parallel rays.

But everybody doesn't possess a lens of accurate known focus, and to meet such a case Mr. Traill Taylor lately proposed an extremely simple and correct method. You focus again two distant objects, and mark on the ground-glass their distance apart. Then

* Concluded from page 345.

remove the lens and replace it by a piece of cardboard with a pinhole in it. As you all know, you will get a view of the scene on the ground-glass, and you shift the ground-glass in and out till the two distant objects are represented the same distance apart as they were with the lens; now the distance from the ground-glass to the pinhole is the focal length of the lens.

I have used the same system myself, only with modified details. I used a view meter, like those sold by Sands & Hunter. I measure, like Mr. Traill Taylor, the distance apart of any two objects as represented on the ground-glass by the unknown lens. Say this is 3". Now, examine the object in the view meter, and slide the front frame in and out till the two objects just fill the field, measure the distance from the frame to the eye; the size of the front frame you know, say it is 2", and the distance you measure and find to be 9".

$$2'' : 3 = 9 : x \text{ the focus required.}$$

$$\therefore x = 13\frac{1}{2}''$$

This system is identical with that of Mr. Taylor, but avoids the pinhole and the slight difficulty there is in seeing any but bright objects, and were the view meter provided with sliding sides, so as to be able to make the front frame equal to the distance between the points taken on the ground-glass, you would only have to measure the distance from the eye to the front frame to obtain at once the focal length.

LYONEL CLARK.

HALATIONS IN NEGATIVES.

CHAPTER III.

It has occurred to me that I have not been sufficiently explicit in my previous remarks respecting the *backing* of bromised dry plates for the prevention of optical halation. After many experimental trials by testing the plates with unnecessarily long exposures on subjects containing strong and abrupt contrasts of light and shade, I adopted the following somewhat indefinite formula for a backing pigment, which fulfilled all my expectations as a preventive of this kind of halation, and at the same time was easily removed from the back of the glass plate previous to development.

Take equal parts of burnt umber (reddish brown pigment) and dextrin (British gum), and intimately mix these with water into a thickish paste—about the consistence of treacle. This mixture is applied to the back of the dry sensitive plates with a broad camel-hair brush. When the pigment has dried they are ready for packing up or for exposure.

If dextrin, or some similar substance, be not mixed with the pigment, some of the particles of the latter are apt to be abraded and deposited on the surface of the sensitive film, where, unless removed previous to exposure, they will certainly give rise to pinholes in the negative. This gummy backing, moreover, is much more easily removed from the glass, previous to development, than would be the case if a simply aqueous mixture were used. Before proceeding to development, a few gentle rubs with a wet cloth or sponge will clear the glass sufficiently well to enable the operator to watch progress by transmitted light and arrest development at the proper time. The late Major Russell was in the habit of employing a broad chisel for scraping off the hard aqueous pigment, until latterly I suggested to him the advantages of mixing the colour with dextrin.

A method adopted by Dr. Hill Norris of finishing his commercial dry plates, was to paste on the back of the glass a piece of thin black paper. This prevented halation to some extent but, as the paper was not in true optical contact, was by no means equal to the plan devised by Russell.

As to the second kind of halation arising from the diffusion of refracted light when passing through the bromised film, I cannot suggest any certain remedy, nor do I think it possible to devise one which would not, if effective for that purpose, entail as great, if not a greater, evil. Staining the film itself, as has been suggested, with a dye impervious to actinic radiations, and one which is washed out in the course of development or subsequent operations, would certainly prevent such lateral and injurious diffusion, but, as has already been pointed out in Chapter I., the remedy would most probably prove worse than the disease. The only available mode of procedure that I can see whereby this kind of halation (*diffusion-halation**) can be greatly reduced, or, at least, ameliorated, is by having a minimum of gelatine and a maximum of bromide in the sensitive pellicle. In cases where small negatives have to be greatly enlarged—to life-size, for instance—this plan would undoubtedly prove beneficial, as a dense negative is not needed, and there are just the class of pictures in which this species of halation

* I have ventured to coin this uncouth compound word for present use in the hope of some one suggesting an equally expressive but more euphonious term.

renders itself particularly conspicuous. In direct photographs it is not very noticeable, unless sharp outlines are inspected with a magnifying glass.

GEORGE DAWSON, M.A., PH.D.

PHOTOGRAPHIC PAPERS AND PAPER MAKERS.

I.

FORTY-FIVE years have elapsed since Fox Talbot brought out the first effective photographic process upon paper, to be quickly followed by the complaints of experimentalists as to the difficulty of obtaining any uniformly trustworthy paper in the market; and as the various paper processes multiplied, so also did the complaints. Herschel, Becquerel, and Hunt, devoted their powers to the examination and testing of various descriptions of papers; nor were they long in discovering that the sizing of the papers had an important and usually beneficial influence, that the most difficult defect to overcome was the presence of minute iron and brass particles, or of specks of metallic oxides in the papers, and that traces of the thiosulphate of soda used to eliminate chlorine after the bleaching of the paper pulp had likewise an injurious effect. They furthermore found out that old papers worked much better than those freshly made, and that unequal absorption of aqueous liquids by a paper was objectionable. The earliest method of examining a new sample of paper was simply to place a sheet of it in water, to take it out after a minute or two, and to hold it between the eye and the light; this at once makes visible, by areas of relative transparency and opacity, to what extent the sheet absorbs water unevenly. To get rid of iron and other metallic spots, a favourite plan was to carefully sponge sheets on both sides with pure water, then to place them in a dish of water with enough nitric acid added to make it slightly sour to the taste; in this weak acid solution it was left for several hours, then was washed for one hour in gently running water. In 1852, Mr. William Crookes published in *Notes and Queries* his method of eliminating iron or brass spots by soaking the paper for two hours in iodide of potassium, one ounce; water, one pint; and enough free iodine to give the solution a sherry colour. In those early times they did not do much in the way of mitigating their difficulties, by coating their papers with special substrata to make them less pervious to aqueous liquids and to keep the photographic image well on the surface, although the waxed-paper processes tended to take this direction.

Another factor had to be considered in those early times about ordinary commercial papers. These sometimes contain foreign matters known as "fillings," which add nothing to the strength or durability of the papers, but increase their weight with or without certain advantages. China clay or kaolin is a favourite substance for the purpose, and it aids in producing a fine surface. Kaolin is not always chemically injurious, but the commoner varieties are liable to contain oxides of iron and other metals, which are bad in that respect. Necessity exists for the abolition of "fillings" in photographic papers, even when not chemically objectionable, because now we have processes which produce pictures more imperishable than any paper upon which they can be printed, so that the amount of permanency of the proofs for historical purposes rests in reality with the paper manufacturer. Cotton fabrics loaded with kaolin have been turned out in Manchester to such an extent as to have largely destroyed the British trade in cotton goods with certain barbarian and Eastern countries, to the great advantage of foreign competitors, and that which renders articles of clothing less durable cannot increase the quality of papers. A photographer who finds "fillings" in his paper has a right to go to the manufacturer and to say, "Your supply contains foreign matters which should be absent," as the dry-plate maker remarked to the water-rate collector when he discovered that he had stewed a frog in his emulsion.

From the first dawn of photography down to the present moment, so far as the manufacture of English papers is concerned, little or no improvement has been made, and any paper turned out at English mills is used, if at all, with innate misgivings by photographers. The effect of this is that thousands of pounds a-year are sent out of this country for the purchase of foreign papers for photographic purposes, made chiefly by two Continental firms, who long ago began to exert themselves to meet a public want. For some time the English makers of gelatine ignored the requirements of photographers after the gelatino-bromide dry plates came into vogue, and only when they discovered that photographic plate makers were buying gelatine from the Continent by the ton did they enter into the competition, but too late to more than partially divert the trade already established. The weight of paper consumed in photography must be infinitely greater than that of gelatine, and the recent great influx of amateurs, by reason of the easiness of the new negative processes, must have given

an additional impetus to the consumption. If any means exist of ascertaining and giving a rough idea of the weight of photographic papers consumed annually in this country, it would be of interest to any English manufacturer who had an idea of trying to meet some of the demand, so that any information the readers of these pages can give upon this point would be of value. A few months ago one of the oldest and most noted photographers in this country, Mr. William England, remarked, while presiding over a meeting of the Photographic Society of Great Britain, that it was a remarkable thing that so much capital has to be sent regularly out of the country for foreign papers, and probably every English photographer is of the same opinion.

My interest in this subject was awakened by the fact that I was practically working out some new iron processes, also some new platinum processes both with and without the conjunction of iron salts, and was impeded in getting good results, in a pictorial sense, by the eccentricity of the effects given by different samples of English papers, and it is hard that scientific research should be retarded by such simple mechanical and commercial obstructions. I bought, at first, a quire of one of the good foreign photographic papers, and found it useless for my purpose, because it was too thin, so that after being soaked in a liquid it would break with its own weight when pinned up to dry. On comparing its retail price with those of some first-rate English vellum-wove papers made from good cotton cellulose, I found that the foreign paper was from four to six times the price for equal weights; for be it remembered that papers are bought and sold by weight, unless in very small quantities. Instead of getting a thicker foreign paper, I resolved to turn aside from the research in hand to learn something about the manufacture of papers, to find out to what extent the prevalent objections to English papers are well-founded, to what extent the objections are merely superstitions because of lack of investigation, and to what extent some defects in home papers can be remedied without difficulty. As the inquiries have gone on, the subject has increased in interest, until at last I do not regret having had to investigate this matter, for the experience gained will always be of use. Just as in engineering it is required that the student shall first go through the drudgery of the workshop, that he may afterwards be the better qualified to perform the higher duties of an engineer, so in photography nothing is lost in the long run by acquiring knowledge about varieties of paper and their methods of manufacture, into which subjects I intend to plunge in the present series of articles.

W. H. HARRISON.

PYROGALLIC ACID AND ITS USES IN PHOTOGRAPHY.

[A Communication to the Edinburgh Photographic Society.]

THE first point that strikes me is the misnomer "pyrogallie acid," for what we know as pyrogallie acid is not an acid, but an alcohol. Some time ago, reading a short article on development in one of the *Year-books*, I was amused to find how the writer strongly insisted on the acid nature of pyro. He was trying to prove that all our development was really acid development—that no matter how much alkali we used, we also had to use an excess of acid before it would act, the acid being either citric, sulphurous, or (save the mark!) pyrogallie.

Without stopping to consider the rather novel views on development enunciated by this writer, I must say that it is a *reductio ad absurdum* proof, seeing that the argument is really based on pyro being a body, and having the properties of an acid, whilst in reality it is of no such nature. Pyrogallol, as it should be more correctly termed, belongs to the same group of organic compounds as carboic acid—also misnamed, by-the-by. They are both alcohols derived from benzene or benzole.

Scientific chemists are fond of speculating as to the arrangements of atoms composing the group, and in the benzene series we have every reason to suppose atoms are arranged and connected one with another in such a way that each earlier atom has the same relation to the other. The graphic method adopted to show this is this:—

Now it is possible, assuming our theories to be correct, to prophesy how many bodies can be produced having the same formulae, and these prophecies stand more chance of being fulfilled than those of a sporting prophet on the Derby.

These theories have been proved to be correct, and many new bodies have been discovered in consequence, which might otherwise have

escaped notice. Such bodies are described in chemical language as isomeric. Theoretically, as regards pyrogallol, we find there should be really three bodies having the formula $C_6H_3.3OH$. All these three bodies have been isolated, and in appearance closely resemble one another. I think here is a field for experiment and research opened up. How could these bodies act as developers?

I have broken the ice a little myself, but not with any satisfactory results as yet; chiefly because, owing to *fitting*, like many others at this season, my dark room is not, I am afraid, quite light-tight as yet, and as my experiments ended, not in smoke, but in fog, I am at a loss whether to attribute it to developer, light, or a combination of either—combined, of course, with the uncertainty of working always connected with new developers.

As regards the names of these others, the pyro, pyrogallol, phloroglucinol, hydroxyquinol, I may say they all act as developers; that is, they are reducing agents.

During the time I have practised photography, pyrogallie acid has undergone two transformations—one in form, the other in price. As a schoolboy I amused myself and tortured my friends with photography, and I well remember having to save out of two weeks' pocket-money whenever I wanted to indulge in pyro. If I remember aright, I paid sixpence for about thirty grains. After leaving school I gave up the art, for I neither had time nor could I carry the enormous amount of paraphernalia about with me when a student. A few years ago, however, I could not refrain from returning to the old love, and commenced by reading up the elements of modern dry-plate photography. I must admit that when I found my old bugbear pyro was the favourite developer, I thought of the expense, but soon discovered that what I formerly bought by the grain, I could now purchase by the ounce without any considerable fortune to back up the expenditure. I enjoyed the luxury of purchasing a whole ounce of pyro, and then found that along with a transformation of price there was one in form. What I purchased as a boy was more compact and less feathery than what we are now familiar with. Formerly I knew it was made by heating gallic acid (hence, in fact, the name) until it lost carboic acid. Considering the price at which it is now sold, I cannot believe that it is made in this way in the present day. I have made some inquiries as to the German method by which pyro is made, but cannot procure any definite or reliable information; the process seems to be very much a secret. There are a number of ways of making it artificially, but only one, to my mind, would account for the cheapness of the present-day article. As thus—

Whether this is the method adopted I cannot say, but of one thing I am certain, that it is not made from gallic acid.

All bodies allied to carboic acid—or the phenols, as they are termed—have the power of absorbing oxygen to varying extents. Phenol turns red on exposure to air; pyro turns brown. In chemical language, they are reducing agents, some more powerful than others. Now, what we call development consists in reducing the salts of silver to the metallic state after they have undergone some change by light; what that change is I do not think any of us can say. The latent image is at present an unexplained mystery. That the change is wholly chemical I do not believe. Be that as it may, a reducing agent applied to an exposed plate has the power of reducing to the metallic state those portions of the silver salt which have received the actinic rays. Used by itself it acts with great slowness, but in presence of an alkali, which absorbs the halogen set free, the action is rapid.

In the chemical laboratory, we use pyro to absorb oxygen in gas analysis, always in alkaline solution.

As you all know, the question of which alkali to use is a somewhat vexed one. Chemically speaking, I cannot see that it matters which alkali is taken; the final result is much the same, although the one developer may produce that result quicker than another.

We are all apt to overlook the fact that a process that succeeds with one man will not do with another. I should say, let each one use the alkali which suits him best, and with which he gets the best results.

As to the unhealthiness of ammonia I am doubtful. The small quantity given off during development I cannot bring myself to believe is hurtful, notwithstanding all that is said to the contrary. I am acquainted with chemical works in which ammonia fumes are constantly present, and in which the workmen are healthy enough. In my own laboratory I have frequently had more ammonia flying about than ever I had in my dark room.

My experience in the matter may not be of much value, but I have tried all the three alkalis, and can develop equally well with either. Soda alone, however, with me gives a red tone, which is rather misleading when judging of printing value.

One thing I never do—that is, keep pyro in solution. To my chemical mind it is impossible to keep it in solution for many seconds without change taking place. When the brown colour is developed after absorbing oxygen a number of complex bodies are present, including acetic acid, carboic acid, &c. Both of these bodies act as restrainers, besides destroying a large quantity of alkali. In fact, the sulphurous acid is the most powerful restrainer I know of. I have saved over exposed plates with a solution of sodium sulphite saturated with sulphurous acid gas, when I do not think I could have done anything with bromide. But sulphurous acid is as unstable a body as pyro. It tends to become sulphuric, or the sulphite to sulphate, and after that stage the solution is useless. I always use pyro dry, and nothing will ever make me change except the introduction of an hitherto unknown preservative. For professional photographers using large quantities of pyro it may not matter so much, but to my fellow amateurs I advise that they should avoid solutions of pyro.

Now a word or two as to the other compounds alluded to in the earlier part of my paper. Phloroglucinol: I procured a small quantity from a benzine compound, and attempted to use it as a developer. It began to develop a picture without any alkali, but almost immediately fog appeared. You could not use ammonia with this body without it undergoing change, but the new substance produced will act as a developer. In my only experiment fog was produced at once; this proves that it has the power, and I have no doubt careful experiment would show us a method by which it might be used. Hydroxyquinol, the other body referred to, I have not had time to make, but I should say that it was even more powerful than either of the other two forms.

Now, I will ask you to observe one thing, namely, the close relationship between these bodies:—

$\text{C}_6\text{H}_4\text{2OH}$ Catechol,
found in the autumn leaves of the Virginia creeper.

T. W. DRINKWATER.

SULPHURATION OF PRINTS.

GELATINE EMULSION PAPERS.

My next series of experiments were with developed prints on various papers coated with gelatine and a silver haloid, against albumenised paper and platinum prints. As the deterioration of albumenised paper prints in the earlier stages is far more due to the yellowing of the whites than to the fading of the images, it was necessary to see if this yellowing would take place when the paper was coated with an emulsion not containing any free silver; at the same time, if there were any yellowing it would be necessary to find out if it were due to something in the paper itself or to a discolouration of the emulsion film on its surface. I may say that I have already commenced a series of experiments in somewhat the same direction as that mentioned in a leaderette in a recent issue of the JOURNAL.

I am trying to discover if there be anything else than bichloride of mercury (a salt for several reasons I would like to do without if possible) which will remove the yellow colour in the high lights of a faded albumenised print. If there is, to see how prints so treated (as well as some prints treated with bichloride of mercury) will afterwards stand against an atmosphere of sulphuretted hydrogen; and then try to find if, by treating freshly prepared albumenised prints in the same way with bichloride of mercury, &c., whether the latter will, by destroying the producing agent of this yellowing of the prints, prevent any such fading action taking place. Printing out gives us such enormous facilities for producing the most satisfactory work, that any amount of trouble might be given to solve these problems.

We know that the papers of many old engravings exposed to light and air have yellowed considerably, and if photographic prints did not yellow any sooner or worse than those, practically we might rest perfectly satisfied; but, unfortunately, we are as yet far from that standard.

For my experiments I took about twenty different samples of papers. It may not be waste of space if I state what they were, because any of your readers who think of making their own bromide papers might like to know what papers can be used which will stand a prolonged exposure to sulphuretted hydrogen without changing colour.

The following were, as far as I could see, perfectly unchanged after a week's exposure in a (humid) atmosphere of sulphuretted hydrogen:—Whatman's hand-made drawing papers; Waterlow's machine-made drawing papers in various sizes from $17 \times 13\frac{1}{2}$ to 40×27 ; Waterlow's Turkey Mill drawing papers in the same sizes; Rives's photographic paper; Waterlow's continuous drawing cartridge, fifty-four inches wide; Whatman's double elephant and imperial drawing cartridge; Waterlow's machine-made cartridge, twenty-six inches by twenty-one inches to forty-four inches by twenty-nine inches.

One of my great objections to many of the bromide and platinum prints I have seen is the chalky whites of the paper, and that is why I tested the cartridge papers. The colour of these is quite different to the yellow tint of faded albumenised paper or platinum prints, and I know many photographic people who would be very pleased if they could purchase bromide papers of a warmer tint than those now sold.

After settling the question of the paper, the next stage was to find if there were likely to be any discolouration in the whites of the prints due to invisible chemical combinations formed before or during development, &c., which would only show itself after prolonged exposure to the light and air. This subject is quite distinct from any fading or change of colour of the silver forming the image. To test this I coated pieces of the above-mentioned papers with gelatino-silver-bromide emulsions (with various proportions of gelatine and silver), and without exposing them to light passed them through the developing and fixing baths, and washed them well. I also took masked portions of prints on "Alpha," "Argentytype," "Eastman," and platinum papers, either produced by the firms manufacturing the papers themselves, or by their acknowledged representatives, some masked portions of albumenised paper prints, some Monckhoven's double enamelled transfer paper used for carbon printing, and a steel engraving from the *Art Journal*.

These were all subjected for nine days to sulphuretted hydrogen in a glass bottle, in the centre of which was a sponge full of water to produce a humid atmosphere. The albumenised papers, of course, had yellowed considerably, the platinum ones were nearly as bad, the enamelled transfer paper had also yellowed slightly, but the Alpha, Argentytype, Eastman, and my own bromide papers were apparently unchanged, as well as the engraving. So we see that as far as the whites in our photographic prints are concerned, coating the papers with emulsion instead of floating them on a nitrate of silver bath is a great step in advance as regards the permanence of their purity, even when organic salts of silver are in the emulsion.

And now for the permanence of the images on these various papers, prints upon each being subjected to the same test. The albumenised paper prints had, of course, faded terribly, those printed from the densest negatives standing much the best. The images on the Alpha paper had faded to a yellow colour, but did not appear so bad as the albumenised paper prints, because the whites had kept pure. The lightest tints were lost. The Argentytype prints had lost a little in density, and had changed from a dense black to a much warmer and not at all an unpleasing colour; indeed, for many subjects it would be an improvement on the original cold black. The half tones were not injured, and the whites were apparently unchanged. The images of the platinum prints were of course unchanged, but the prints had deteriorated a good deal in appearance through the yellowing of the surface of the paper. This can be removed by chlorine water, and I intend to try by putting a fresh prepared platinum print into chlorine water whether the latter will destroy the producing cause and prevent any future yellowing of the print by sulphuretted hydrogen. If it will, it will only be necessary to pass the prints through chlorine water, and wash them before mounting.

My own bromide prints gave various results, I believe due to the different proportions of iron and oxalate of potash used in the development; but it will be necessary to carry out a fresh series of experiments to solve this question. Some of them were as nearly as possible identical with the Argentytype prints, others had changed to a sepia colour, but in none of them had the lightest tints been destroyed, and the whites were very pure.

Undoubtedly, in my hands the Eastman prints stood the best of them all, taking into consideration the purity of the whites and the density and colour of the blacks and half tones. Indeed, the same sulphuration test which practically destroyed the albumenised paper prints, and had changed the others as I have mentioned, had improved the Eastman prints, because it had given a slightly richer and warmer tone to the blacks without the slightest reduction of their density.

Were they not produced by a blind process requiring development, I would consider that the Eastman Company had solved the problem

of photographic printing. If we could only get the same results by *printing out*, it would be good-bye to all others, at least as far as I am concerned.

HERBERT S. STARNES.

DALE ABBEY.

[A Communication to the Derby Photographic Society.]

FIFTY years ago, Richard Howitt, the poet, a native of the neighbouring village of Heanor, wrote some verses entitled *The Hermit of Dale*, in which he says:—

"O Deepdale! lovely is thy land
With pasturing herd and flock;
And lovely is thy Hermitage,
Cut in the solid rock.

"A cheerful place of healthful life—
A spot of Nature's love;
With greenest grass up to the door,
And crowned with trees above.

"With that one arch before thee set—
That one old Abbey window fair;
The only wreck of the rich Fane
That restless time would spare."

And there is little change here to this day. Dale Abbey lies buried amongst the woods and fields in a secluded valley, far away from the "madding crowd;" and though the Great Northern Railway has made it more accessible than heretofore, there is a quaintness about it speaking of the past, and realising the idea of an old English village enjoying the calm and tranquillity of bygone years. It is true that the grey old guest-house disappeared nearly four years ago to make room for the present building—a change to be deplored by every lover of the beautiful, especially as it might have been carefully repaired, and its old form and features retained. You will see by these photographs—some of them taken only just *one* day before the work of destruction commenced—what a charming old place it was. The field where stands the old Abbey window has been excavated, and the foundations of the walls, pillars, &c., exposed to view, increasing our knowledge of the building, and bringing to light many matters with which we were not previously acquainted. The old yew-trees, coeval with the sacred edifice near which they stood, have gradually disappeared, and not a vestige of them now remains. I have brought photographs of these subjects, taken before and after the diggings. The churchyard was formerly hedged round on the north and west sides, and the brook connecting the old fishponds was crossed by a little ford and a plank footbridge, instead of the arched bridge as now. For nearly half a century have I made constant pilgrimages to Dale Abbey, and these are the principal changes I note. The old-world place remains much as it was when the poet wrote—

"Here, as to all the world unknown,
A sage seclusion dost thou keep;
And here Antiquity enjoys
A deep and mossy sleep."

This seclusion was somewhat rudely, though reverently, disturbed on the 9th of September, 1878, by some of the members of the Derbyshire Archaeological Society, when the excavations commenced, and were again renewed on the 2nd of July in the following year. The results of our labours—for I was one of the disturbers—you will see on the site, and those who take interest in archaeological matters may find an account of our diggings in Vols I. and II. of the Society's *Journal*.

The Abbey of the Blessed Virgin Mary at Dale was founded about 1160, by Serlo de Grendon, Lord of Bradley, as a Monastery of Austin Canons, who were afterwards replaced by Præmonstratensians. Indeed, there were many changes which I have not time to tell of. Some of the canons, being idle and addicted to the pleasures of the chase, were turned out by the King; others could not live there in poverty, after hunting the deer was stopped, so returned to their former homes. Towards the close of the twelfth century, however, some members of the De Grendon family endowed the monastery, and placed it in charge of nine canons from Newhouse, in Lincolnshire; and from this time, under eighteen successive abbots, the place prospered and increased in wealth and lands, and at the dissolution of monasteries, in 1539, it had sixteen canons with a yearly revenue of £144 4s., equal to about £3000 at the present time. The original structure has almost entirely disappeared, and the remains you now see are parts of a magnificent building begun about the year 1200, with later additions extending over nearly two centuries. We shall not have time for a detailed description, for I must say a few words about the Hermitage on the hillside yonder; suffice it, that the Abbey of Dale was once a noble building of great extent and beauty, as you may judge from the disclosed foundations, the grand old window-arch, and other remnants still standing *in situ*—as parts of the kitchen and the gate-house.

One of the canons of the Abbey has left us a most interesting chronicle, the original of which is in the British Museum. A good translation of it will be found in Glover's *History of Derbyshire*. This canon, Thomas de Musca, divides his chronicle into thirteen chapters, each beginning with

one of the letters of his name, forming a sort of acrostic. Chapter III., "Concerning the Baker who became a Hermit; the First Inhabitant of Deepdale," gives an account of the origin of the Hermitage, as related to him by "a noble matron, the Lady Matilda de Salicosa-Mara," one of the founders of the monastery. I wish there was time to give this legend in his own words. It relates that a baker of Derby, Cornelius by name, and living in the parish of St. Mary, "a religious man, fearing the Lord, and much intent upon alms and good works," fell asleep "on a certain day in autumn" at the hour of noon, when the Blessed Virgin Mary appeared unto him in a vision, and bade him, if he were disposed to become a perfect man, to leave all his worldly possessions behind him, and go to Deepdale, there to serve her and her Son in solitude. He was miraculously directed to the place, to which he was previously an entire stranger, by a maiden, whose mother he overheard directing her to drive some calves there. He found it a cold, marshy, and desolate place, and here "he served God day and night, in hunger and thirst, in cold and meditation."

"Here in the hollow oak he made
His dwelling night and day,
Whilst he with unrelenting hands
The hard rock cut away."

I need not describe the Hermitage, for you have seen it, and got some good views of it too, I hope. The country round about is much changed since the Derby baker came here, but the Hermitage is very little altered, though a stockinger did once make it his home. The surrounding trees are of comparatively recent growth, but here and there you will find a hoary trunk, the last lingering relics of the primeval woods. In the dim old days of which I have been speaking, the valley of Deepdale was a wild and lonely spot in the midst of a great forest extending from Derby almost to Nottingham—well stocked, we may imagine, with deer and other wild animals. However that may be, "a certain potent lord, of the name of Radaolphus, the son of Gremund, and lord of the moiety of lands of Okebrook and Alvaston," returning from Normandy, took it into his head to have a little sport in these woods, and whilst hunting, was attracted by the smoke of the poor hermit's fire curling up through the trees, and wished to know who dared, without license, make a "mansion" in his forest. But on seeing the wretched Cornelius, clothed in rags and skins, he was "smitten at the heart," and granted him the place, together with the tithe of the mill at Borrowash, for his sustenance. Here he battled bravely with the devil, who envied this good man his peaceful and religious life. Cornelius also suffered greatly from the want of water, and discovered a spring in the deeper valley, close by which he built an oratory in honour of God and the Blessed Virgin, where "he wore away the sufferings of his life, laudably, in the service of God." The well is still to be seen at the bottom of the orchard, to the north-east of the church, and is still known as the Hermit's Well. Another legend in the same chronicle relates how the site of the Abbey was fixed upon through the vision of "one Uthlagus, a very famous man," who was sleeping and dreaming on Lyndersyke, the hill you see to the west of the Abbey, when he beheld a golden cross standing in that spot where the foundation was afterwards laid.

There is a tradition extant amongst the inhabitants of Dale, that so long as the Abbey arch stands they are exempted from payment of tithe. Another, that treasure of great value lies buried in the Abbey fields, though we came not across it in our diggings; graves there were in plenty,* and archaeological treasures not a few, but no treasure-trove! The last and most popular legend I shall give you, is that telling of how the King granted to the Abbot of Dale as much land as he could encircle in one day with a plough drawn by deer caught in the forest, as shown in one of the windows in Morley Church, removed from Dale. This window, however, represents the well-known story of St. Robert of Knaresborough, and once adorned the refectory of Dale Abbey.

The quaint old church here, one of the very smallest in England, boasts of great antiquity, and is on the site of the oratory built by the hermit, if, indeed, some parts of it are not of the original structure; and small though it be, you have seen that it has a nave, chancel, side aisle, screen, and gallery—the latter of comparatively recent construction, and reached by steps on the *outside* of the building. The pulpit in the corner is certainly not of the "Perpendicular" order, the communion-table is unique, and the bishop's chair quite a Brobdingnagian feature in this Lilliputian church. The font, after various vicissitudes, has settled at last in the east end of the aisle. I remember the time when it did duty as a flower-pot in the vicar's garden at Stanton; then it was brought here and placed in the north-west corner of the churchyard, close by the gate; and, finally, came to rest in its present position. The carving on two of its sides of the Virgin and Child, and the Crucifixion, is of good design and execution. This font belonged to the Abbey. The guest-house next door once seemed to form part and parcel of this sacred edifice, as you may see in these old photographs, and the writer of *All About Derbyshire* says, "I defy you to decide where the church ends and the house begins." There no such difficulty now. In the old house you might have seen a blocked-up doorway, once opening into the church. It was closed because

* "I have heard it said by a man of veracity, worthy of belief, that more than four hundred warriors lie buried in that place, setting aside others of the nobility and gentry, and a prodigious number of common people."—*Chronicle of Thomas de Musca*, VIII., 6.

the singers and others sometimes got tipsy. For you must know it was a public-house at the beginning of this century called the "Blue Bell." I have seen the signboard.

And now I must close my rambling recollections by telling you that relics of the Abbey exist at Radbourne, Chaddesden, and Morley churches. In the latter are the interesting series of stained glass windows I have before named. Morley and Breadsall would make another good afternoon's work for us, as some pretty bits could be got at either place, though the latter has suffered much from an artist's point of view since the railway station perched itself there. I do not go so far as Ruskin in my distaste for railways—for do they not carry us easily and cheaply to places we should never have dreamt of seeing without their aid?—but I would recommend you to hasten with your cameras to any historical or lovely spot when it is threatened with a railway station for its near neighbour, for as surely as it is built, so surely will hordes of trippers devastate the neighbourhood, and ugly houses rise around to deform the landscape. Just one more piece of advice and I am done. Photograph any and every old church or other ancient building you may come across before the "restorers" fall upon it and take away its beauty. Long may it be before the rude old church of Dale is "restored" and revived, or destroyed as the adjoining house has been!

RICHARD KEENE.

LITHOGRAPHY IN HALF TONE.

HUSBAND'S PAPYROTINT.

THIS process is specially adapted for the reproduction of subjects in half tone, such as architectural drawings in monochrome, or subjects from nature, and it is inexpensive. Its advantages over other methods of half-tone photo-lithography are, that a transfer can be taken in greasy ink, for transfer to stone or zinc, direct from any negative, however large, without the aid of a medium, the grain or reticulation being obtained simply by a chemical change. The transfer paper being in direct contact with the negative, the resulting prints are sharper than by those processes where interposed media are used; whilst the same negative will answer either for a silver print, platinotype, or a transfer for zinc or stone. The advantage of being able to use a non-reversed negative is very great now that gelatine plates have so largely superseded those made with collodion.

The method of manipulation is as follows:—Any good surfaced paper is floated on a bath composed of—

Gelatine (Nelson's flake).....	8 ounces.
Glycerine	1½ "
Chloride of sodium (common salt)	2 "
Water.....	50 "

Great care should be taken that the solution is not overheated, and that the paper is coated without bubbles. It is then dried in a temperature of 60° Fahr. The paper will take about ten hours to dry, and in this state will keep for years. When required for use, it should be sensitised by floating, or immersing, in a bath of—

Bichromate of potash	1 ounce.
Chloride of sodium	½ "
Ferri-cyanide of potassium	100 grains.
Water.....	30 ounces.

This need not be done in the dark room, as the solution is not sensitive to light.

The paper, after sensitising, is dried in a temperature of 70°, and in a dark room. When dry, it is exposed under any half-tone negative, in the ordinary printing frame. It is preferable to print in sunlight, and, for negatives of medium density, an exposure of three minutes is required; but the exposure will vary according to the density of the negative. The correct time of exposure can best be judged by looking at the print in the frame. When the image appears on the transfer paper of a dark fawn colour on a yellow ground the transfer is sufficiently printed. It is put into a bath of cold water for about ten minutes, until the soluble gelatine has taken up its full quantity of water; then taken out, placed on a flat piece of stone, glass, or zinc plate, and the surface dried with blotting-paper.

The action of the light has been to render the parts to which it has penetrated through the negative partly insoluble, and at the same time granulated. A hard transfer ink is now used, composed of—

White virgin wax.....	½ ounce.
Stearine.....	½ "
Common resin	½ "

These are melted together in a crucible over a small gas jet, and to them are added four ounces of chalk printing ink, and the mixture reduced to the consistency of cream with spirits of turpentine. A soft sponge is saturated with this mixture, and rubbed gently over the exposed paper (in this stage the nature of the grain can be best seen). An ordinary letterpress roller, charged with a little ink from the inking slab, is then passed over the transfer, causing the ink to adhere firmly to the parts affected by the light, and removing it from the parts unacted upon. It will be found that with practice, rolling slowly and carefully as a letterpress printer would his forme, the ink will be removed by the roller according to the action that has taken place by light, leaving the shadows

fully charged with ink, and the high lights almost clear, the result being a grained transfer in greasy ink. The transfer is next put into a weak bath of tannin and bichromate of potash for a few minutes, and when taken out the surplus solution should be carefully dried off between clean sheets of blotting-paper. The transfer is hung up to dry, and, when thoroughly dry, the whole of the still sensitive surface should be exposed to light for about two minutes. A weak solution of oxalic acid should be used for damping the transfer (about 1 in 100), and this should be applied to the back of the transfer with a soft sponge. After it has been damped about four times, it should be carefully put between clean sheets of blotting-paper, and the surplus moisture removed. A cold polished stone is then set in the press, and after everything is ready the transfer is placed on the stone and pulled through twice. The stone or scraper is then reversed, and the transfer is again twice pulled through. A moderate pressure and a hard backing sheet should be used, care being taken not to increase the pressure after the first pull through. The transfer is taken from the stone without damping, when it will be found that the ink has left the paper clean. Gum up the stone in the usual way, but if possible let the transfer remain a few hours before rolling up. Do not wash it out with turpentine, and use middle varnish to thin down the ink.

It should have been mentioned that varying degrees of fineness of grain can be given to the transfer by adding a little more ferri-cyanide of potassium in the sensitising solution, and drying the transfer paper at a higher temperature, or by heating the paper a little before exposure, or by adding a little hot water to the cold-water bath, after the transfer has been fully exposed; the higher the temperature of the water the coarser the grain will be. The finer grain is best suited to negatives from nature, when a considerable amount of detail has to be shown.

The coarse grain is best for subjects in monochrome, or large negatives from nature, of architecture, &c., where the detail is not so small. Even from the finer grain several hundred copies can be pulled, as many as 1200 having been pulled from a single transfer, and this one would have produced a great many more if required.

—*Photographic Journal.*

WHERE I WENT WITH THE CAMERA.

NO. VIII.—ANTWERP.

My next stay was at Antwerp, and the last on the journey. It is a sea port of considerable importance. Away down by the harbour, with its miles of shipping and intersecting canals, there is a breezy, open, free air, that smells of tar, and ropes, and ships—the very atmosphere suggesting the sea. In this district, down by the quays, very interesting studies in marine subjects are to be had on every hand. The city itself is rich in historical associations, fine streets, notable churches, and valuable paintings. In some of the old, out-of-the-way streets I found good pictures—Catholic shrines in bas-relief and faded colourings, quaint, old, and decayed places where devotees used to kneel and pray now passed by unheedingly; that which in former days was approached with love and reverence, now left rotting over cellar doors.

St. Paul's of Calvary is a church that contains within its grounds some original features for the camera. The story of the Crucifixion is rendered in rough sculpture built up in the grounds of this church, with rocks for hills and figures life-size; under the Hill of Calvary, in a cave, is placed the body of Christ lying in the sepulchre. With the exception of this latter, which is in considerable darkness, all the other scenes depicted are out in the open and can be easily photographed. The cathedral of Antwerp is known all over the world for its magnificence as a building, and for the wealth of paintings covering its walls. It is in rather a confined situation for making effective pictures.

From the spire of this cathedral Quintin Matsys is said to have fallen and been killed—falling close to the iron ornamental fountain that he himself had made, and which now stands in the square. He is said to have been up repairing the spire; but I fancy that this must be a fable, for he never seems to have done blacksmith work after he became an artist. It is said that it was the power of love that made him leave the anvil for the brush, and his success was so complete that he gained the lady and, as an artist, world-wide fame.

Points of interest, such as the Museum, the Rubens' pictures, Rubens' house, the Stadthouse, &c., cannot be well overlooked by any visitor; but there is a small museum at Antwerp that I would like specially to draw attention to, if ever you visit this city. It is called the "Plantin Museum." In these days of photo-mechanical printing and engraving by all the various processes—to all who take an interest in such departments—this museum will be found a special attraction; not that the printing or processes here have anything to do with photography, but as one of the handmaidens of the past, showing what had been done in these early days in engraving and printing, the collection will be found wonderfully interesting.

First copies of books, designs, illuminated alphabets, engravings, copperplates, woodcuts, original manuscripts, and autographs, dating back to the fifteenth century, and all gathered together in the house that was Plantin's home. It seems like a fairy tale. Upstairs and downstairs, flat after flat, as his stores of treasures grew upon him he still added

parts to his house, and here, in the nineteenth century, you will find the rooms he lived in just as he inhabited them in the sixteenth. The bedroom—and the bed still there—the kitchen, and the tools he used to work with, the library and the books he used to read. And the marvel is, that how, in the midst of such a checkered life, Christopher Plantin was enabled to build this monument for himself, which will last as long as his country and its people.

Christopher Plantin may be said never to have had any money but what he himself made. When quite a lad his father left him at Paris to get his education, and seeming to forget all about him left him for good. As the school fees were never forthcoming, and the boy was thrown on his own resources, he was compelled to leave school, and got a situation as assistant to Robert Mace, a printer of some note, at Caen, Normandy. Here he resided for some years, and here seems to have been born that intense love for books. However, he laid it aside for a time, for, coming to Paris, he started a business to emboss leather, and gild and illuminate it, for bookbinding and kindred works. He came to Antwerp in 1549, and made it the city of his adoption, continuing here for a time this business of leather dressing, bookbinding, and jewel-case making, and gained a very high reputation for gilding and enamelling on leather.

At this time an accident occurred that changed the current of his life. One night, in the darkness, Plantin was taking home a small jewel case which had been specially ordered by Gabriel de Cayns, Secretary to Philip II.; so particular was it that Plantin had been desired to bring it himself. On the way he was set upon by several men masked and armed, and left on the ground wounded and nearly dead. The masked party had been waiting in ambush to attack an enemy expected to pass that way, and Plantin being mistaken for their victim was ent down. No sooner did the perpetrators of the deed see their mistake than they fled. He was so ill after this encounter that he was unable to resume his business, and falling back upon his knowledge of printing began that as his trade for the future. He was not long at this new employment, however, before he was accused of publishing heterodox works, and for safety he fled to Paris, where, one of a company, he for some years carried on a printing business. Heterodoxy here also seemed to make living unsafe, and he renounced the company and chose an orthodox pathway for the future, returning to Antwerp. In 1567 he published a Bible according to the authorised version of the Council of Trent, and by the Pope's authority he was privileged to sell it; but trade being unsatisfactory he left Antwerp again, and did not return till 1585, when he stayed for good.

The King gave him very extensive orders, which he would have been better without, for he never paid anything for them, neither to Christopher Plantin nor his successors. The King also awarded Plantin a pension, but it never was forthcoming. The money to pay it was to be obtained from the confiscated estates of the Prince of Ghent, but the estates were given back, and hence the source from which the pension was to flow being dried up he never got it.

And still, amidst all these vicissitudes, he managed to build up this collection, so wonderful in its completeness, in this house where he lived and died, and which the family, generation after generation, have cared for and kept on till 1876, when it was bought and became one of the institutions of the country. Do not miss going to see it. It will be a day well spent.

I got on board the boat at Antwerp, and being early put up my camera and made a few exposures. I then packed up my traps and laid them away. In the cool of the summer evening, sitting on the deck as we sailed homeward, I was looking over the pages of my diary of the past few weeks before I closed the journal, and the variety of people one meets struck me as strange as the variety of places. I find noted:—

"In the carriage in which I am comfortably seated there is rather an eccentric young (?) lady. She talks loud and lets everybody know her business. She is bound for the Hague. She insists on filling up the window as she talks on. The old man outside, who looks like a battered ruin, is her father. She pulls a cigarette case out of her pocket and insists upon his taking one; she next furnishes a match box and lights it for him. 'And now, pa,' says the giddy soul, 'my book will be published in a fortnight; the first issue is thirty thousand copies, and, remember, pa, when I come back it will be out, and won't we have such a day at Brighton.' Again and again the old man was assured of that till the train started.

"In the corner of the carriage sat a ponderous daughter of Israel, whose only travelling gear seemed to be a little handbag. Some Jewish people saw her away, and she talked with every questionable character on the journey. In the boat she preferred the steerage to the cabin, and talked and chatted with every servant on the route. She was evidently doing business, but whether in diamonds or rabbits' skins one could not guess.

"The young lady with the spectacles is going to Germany to work as English governess—and in return they are going to *finish* her,' she says.

"On the train over here I met the Christmas-eard man, who had travelled with his wares as far as St. Petersburg, and who was now on his way home to Berlin.

"I saw a little Frenchman who had travelled all the way from Moscow, and in that second-class carriage; he had been three days and three

nights without stoppage, and as he was going on to Paris he had another twelve hours to travel. He had gone this journey sixteen times already, and he was not yet twenty-four years of age.

"The cheery priest from Ireland with his dull pupil I met doing the journey to Rome. The English nobleman in disguise I met—he who sits reading what he would have you believe were State despatches, and haw, haws, all round, filling up the carriage with what the Irishman calls promiscuous ostentation."

It is getting dark. I close the book.

PATENTS COMPLETED.

IMPROVEMENTS IN VIGNETTE PAPERS FOR PHOTOGRAPHY.

No. 9155. GEORGE JOSEPH SERSHALL, 371, Lodge-road, Hockley, Birmingham. July 14, 1886.

This invention consists of a new and useful method of making vignette papers for photography, as hereinafter described. By my method the paper is printed by lithography, or other suitable means, on both sides; one side with red ink and the other side with yellow ink; the gradation of tint from the solid colour to its faintest edge being obtained by means of stipple, spottle chalk, or otherwise; or, instead of red and yellow inks, any other two suitable colours may be used; or the paper may be printed, as before named, on one side only in any non-actinic colour for the same purpose. After the printing is completed it must be thoroughly dried, and then the paper must be rendered transparent by varnishing one or both sides, or any other suitable means, and when the varnish becomes hardened the paper is ready for use; or, if preferred, the paper may be rendered transparent before being printed on.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—Producing vignette papers by printing by any suitable method non-actinic colour on to one side or on to both sides of paper already transparent, or to be rendered transparent in the required parts after printing as herein described.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, June 2nd, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. J. Traill Taylor presided.

The CHAIRMAN remarked that the Cellerier Syndicate had invited the inspection of their process that day in relation to what they called photography in natural colours; he and Mr. T. Bolas were among the members of the press who consequently attended. The specimens exhibited were merely coloured photographs, and upon being told that the description of the photographs publicly made was misleading, they replied that if so it was unintentional on their part, and they would alter the title of the Company. He found that to see the working of the process he would have to leave London for Sidcup, and that being inconvenient he had not gone there. He asked them in what their method differed from Ashton's process, and they replied that they could cement the pictures; he replied that that had been done before. They said, "Well, these are in carbon," and he replied, "So are the Woodburytypes."

Mr. A. L. HENDERSON said that the Autotype Company had once turned out carbon photographs backed by coloured *papier minéral*; they had much the appearance of old oil paintings. Léon Vidal had exhibited some beautiful photographs taken by one of this class of processes at the last International Exhibition in Paris.

The CHAIRMAN added that Vidal had applied the same principle to some beautifully executed portraits, and that a detailed account of his process had been published in *The Popular Science Review*. One difference between Mayall's and Cellerier's process was, that Mayall had not floated a company yet. Mayall had not sent him yet the photograph for which he sat; perhaps no colours could be found to suit his features.

Mr. L. MEDLAND read the following extract from *The Family Doctor*, No. V., Vol. I., April 4, 1885:—"Photographic Printing in Colours.—Paint by hand, with transparent colours, an ordinary negative. 1. Take a piece of

ordinary sensitised paper and wash it to remove any free silver nitrate. 2. Place the washed paper in a solution of protochloride of tin, and expose to weak light until the silver chloride is reduced to subchloride and the paper assumes a uniform grey colour. 3. Float the paper on a mixed solution of chromate of potash and sulphate of copper, and dry in the dark. The paper is now sensitive to all the colours of the spectrum, and by printing upon it with a coloured negative the colours of the negative will be reproduced. After printing, wash with cold water and dry."

The CHAIRMAN remarked that the statements just read were true; it was Becquerel's process, but scarcely explicitly enough stated. If it could be quickened sufficiently for the camera it would be one of the steps in the direction of photography in natural colours. The best thing done yet was by Carey Lea, who, with subchloride of silver, had certainly obtained colours.

Mr. J. B. B. WELLINGTON exhibited some of the red chloride of silver spoken of by Mr. Carey Lea. He said that it was sensitive to light, that it consisted of chloride and subchloride combined, and that it was not soluble in nitric acid, but would dissolve both in ammonia and hypo. He exhibited a piece of paper coated with it, with a print of Warnerke's sensitometer screen thereupon.

Mr. HENDERSON thought that the image had really been produced, as usual, in chloride present, and not in the subchloride.

The CHAIRMAN said that Becquerel, with red chloride of silver upon Daguerreotype plates, had obtained photographs in natural colours.

Mr. HENDERSON moved a resolution to the effect that that Association considered the title of Cellier's process to be misleading, that the process was not novel, and that this should be notified to the public.

Mr. A. MACKIE seconded the motion, which was then passed.

A question in the box asked what was the action of the infinitesimal proportion of chloride of lime, one grain to a quart, recommended for toning prints.

Mr. HENDERSON thought that such a small proportion would have no effect at all.

Mr. YORK had been trying it, and could not find that any effect was produced.

Mr. HENDERSON supposed that a trace of chloride of lime might help to keep the whites clear.

The question was asked why citric acid tended to preserve sensitive albumenised paper.

Mr. W. H. HARRISON believed because most acids resisted deoxidising influences in photographic processes. Ferric salts had a tendency to be deoxidised directly by light and other influences. The haloid salts decomposing under light and other influences tended to deoxidise water, and the oxygen then attacked any organic matter present.

Mr. W. M. ASHMAN objected that ready sensitised paper printed as fast as other paper.

Mr. HARRISON thought that in any such cases the relative power of light was so strong that the resisting power of the acid was not noticed.

Mr. J. J. BRIGNSHAW found that steeping prints in a very weak solution of washing soda greatly facilitated toning.

Mr. MACKIE believed that there was gum in most of the ready sensitised papers. Mr. W. K. Burton had found gum and citric acid formed one of the best mixtures for preserving sensitive papers.

Mr. HENDERSON believed that anything of the nature of a varnish tended to have that effect. If a ready sensitised paper were prepared on the principles he had publicly laid down for his "argentic stain" some time ago, it would be likely to have excellent keeping qualities.

Mr. HERBERT STARNES had prepared some plates according to Mr. Henderson's published formula, and they went brown at the edges.

Mr. BRIGNSHAW had some which had been prepared with it, and had kept perfectly.

Mr. JAMES ERNEST BROWN, of Melbourne, upon being invited to speak, said that he had not been long in England, but so far had seen nothing above good Australian photographic work, except that in Melbourne no one was yet turning out burnt-in enamels or producing photo-lithographs; not much, also, was doing in carbon printing. The Australian opal pictures were mostly produced by the old silver wet process; he thought that in time carbon would be substituted. Melbourne was the largest city by far in Australia and the chief photographers in it were Messrs. Johnstone, O'Shanessy, & Co., Limited, and Monsieur Gronzelle. Photographic societies had been started there, but they had died out because of small quarrels and bickerings; he believed that there was now no photographic society in Victoria. Prices were higher in Melbourne than in London, but the high duty on photographic goods made higher prices necessary. *Cartes* in Melbourne were turned out from 7s. to nearly £1 per dozen, and cabinets at from 10s. 6d. to £1 per dozen; for larger pictures there were no standard prices. In Victoria people demanded paper pictures with a gelatinous or other glaze, which he thought to be very bad taste. About half the photographers in Melbourne stuck to the wet plate process. They had one manufacturer of dry plates, and his plates were excellent in quality.

The CHAIRMAN thought from the specimens exhibited to the meeting by Mr. Brown of his own work that Australians had nothing to learn from London in the way of artistic portraiture. Once he had received a very good specimen of a vitrified enamel from Australia, but had forgotten whether it came from a professional photographer.

Mr. ASHMAN then introduced Mr. C. Wood, of Stanford, Kent, to the meeting.

Messrs. Medland, Smith, and others, then exhibited photographs they had taken during the recent excursion of some members of the Association to Chiddingstone, Kent.

The HON. SECRETARY remarked that the train on the South Eastern Railway took three hours to get there.

Mr. MEDLAND could not understand why halation appeared in one of his plates.

Mr. HENDERSON responded that the tendency of the times was for plates to get more and more thinly coated with emulsion.

Mr. Wellington exhibited platinum prints of views taken at Leatherhead.

Mr. STARNES exhibited the results of some experiments he had made as to the comparative permanency of prints. He had cut a piece off each print and

placed it for nine days in a closed bottle containing sulphuretted hydrogen gas and a wet sponge. The platinum prints yellowed, Fry's bromide prints stood pretty well, and the Eastman prints best of all. In all the bromide pictures he had so tested, and there were many prepared in different ways, the whites had kept clean. He fancied that the Eastman paper contained some platinum.

Mr. HARRISON thought that in the instance before them due care had not been taken to get all the iron salts out of the platinum paper by sufficient temperature or length of immersion in the hydrochloric acid baths.

The CHAIRMAN had found some paper for development printing, issued by Marion & Co., to be extraordinarily sensitive.

Mr. ASHMAN wished that Mr. Starnes would try the influence of sulphuretted hydrogen upon blue iron prints.

The CHAIRMAN said that there were hopes that special railway facilities from London would be given to attend the Convention in Glasgow early in July.

The HON. SECRETARY said that several invitations had been received from different towns, inviting the Convention to hold its meeting in them next year.

The meeting then broke up.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the above was held at the Technical Schools, Bridge-street, on May 26,—Mr. W. J. Harrison, F.G.S., in the chair. There was a good attendance.

The minutes of the last meeting having been duly read, Messrs. A. Atkins, Jarvis, and G. Barton, were nominated for election as members.

The report of the excursion to Lichfield was read by Mr. A. PUMPHREY. In it was mentioned that one hundred and seventy-seven pictures were obtained, amongst them being some of Eastman's stripping films and also Pumphrey's flexible films. A very enjoyable day was spent, there being plenty to be taken by the camera; in fact, a number of the members went over for a second time, not having secured all they wished on the previous visit.

A large number of prints were shown by Messrs. Harrison, Hendren, Harold Baker, B. Karleese, Dutton, Pettitt, Thomas Taylor, Thomason, and J. H. Pickard, some of the views and interiors of the cathedral being very fine.

Mr. W. OSBORN then read his paper on *Reminiscences of Photography*, giving his experiences as an amateur photographer for the last twenty-five years, having gone through most of the processes from the Daguerreotype and calotype up to the present dry plates. He described the same, and gave a most valuable and instructive lecture to his listeners, finishing with a biographical account of the old pioneers of photography in Birmingham, foremost of whom stood the Society's President, Dr. Hill Norris, the original inventor of the dry plate processes.

Mr. PUMPHREY read a paper on *A Multiplex Dark Slide for Card-Mounted Films* [this will appear in a future number].

Mr. Welford then exhibited a number of cameras and shutters, and other apparatus, lent to him by various firms, notably amongst which were a detective camera by Newton & Co., Liverpool, and Newman's automatic shutter. He also showed street views and crowds he had taken the same day with the detective camera, which were remarkably good.

The meeting terminated with the CHAIRMAN announcing the excursion on May 30 to Millers Dale, Derbyshire; also the paper for June 23, *Printing by Artificial Lights*, by Mr. F. Birkett.

DERBY PHOTOGRAPHIC SOCIETY.

THE members of this Society, to the number of twenty, paid a visit to Staunton Harold and Calke Abbey on Saturday last, by the kind permission of the Right Hon. the Earl Ferrers and Sir V. H. Crewe, Bart., under the leadership of Mr. J. W. Price. The journey was made by brake, starting from the General Post Office shortly after two p.m., the weather being all that could be desired. On arrival at Staunton Harold the party took negatives of all the most interesting spots about this beautiful estate, and then proceeded to the "Saracen's Arms," where they were met by Mr. Leadbetter and Mr. Chapman (the respected stewards of Earl Ferrers and Sir V. H. Crewe), who entertained them at a most sumptuous and excellent tea, to which the members did ample justice, and a hearty vote of thanks was accorded to these two gentlemen for their kindness in providing such an unexpected treat. After tea a large group was taken on a 15×12 plate by Mr. Roberts (one of the members), also by Mr. Price and Mr. Keene. The journey to Calke Abbey was then continued, where some more plates were exposed, and the party returned to Derby at about a quarter to ten, having thoroughly enjoyed a most successful excursion.

HALIFAX PHOTOGRAPHIC CLUB.

THE monthly meeting of the above Club was held in the Mechanics' Hall on the 26th ultimo,—Mr. B. Rowley in the chair.

Mr. W. CLEMENT WILLIAMS gave a lecture and demonstration on the carbon process. The great simplicity and beauty of the process received the full admiration of all present, and many decided to adopt it at once. The general impression had been that the carbon process was a difficult and tedious one, but, as demonstrated on this occasion, the expression of opinion pointed to the opposite conclusion.

A very hearty vote of thanks was passed to the Lecturer, and also to the Autotype Company for the very great treat they had afforded the Club in sending for exhibition a large number of beautiful carbon pictures; as the President aptly remarked, quite a fine-art gallery.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE eighth ordinary meeting of the current session was held in the Professional Hall, George-street, on June 1, at eight o'clock, the President occupying the chair.

Mr. George Stewart was elected as an ordinary member.

Dr. THOMAS W. DRINKWATER read a paper on *Pyrogallie Acid and its Uses in Photography* [see page 359], which was highly appreciated, and was the subject of discussion.

Mr. J. M. TURNBULL said he preferred to keep pyro in solution for development, because it was more convenient. It doubtless oxidised a little, but with the addition of sulphite of soda and sulphurous acid, and when kept well stoppered, it remained perfectly good for a long time. He had seen excellent negatives developed with it, even after the solution was twelve months old.

Mr. JAMES JAMESON entirely agreed with Dr. Drinkwater in using dry pyro. A solution began to change from the moment it was made up, whereas when used dry it could be depended upon to produce precisely the same results in each case and at any interval of time.

Mr. A. A. INGLIS found the Ilford Company's formula work well in his practice.

Mr. JAMES CRIGHTON developed with two stock solutions.

Dr. DRINKWATER replied to some remarks made in reference to the manufacture of pyro, and reiterated his preference for keeping it in a dry state. He recommended a means of measuring it for use contrived by Mr. Jameson some years ago, namely, a graduated glass tube in which a sliding pencil-shaped piece of wood is adjusted. The tube is simply dipped into the dry chemical and takes up exactly whatever quantity is desired.

The SECRETARY intimated that a strong desire had been expressed for one or more outdoor meetings on the Queen's Jubilee holiday, the 17th instant, and that Dunfermline, Dollar Glen, Roslin, and St. Andrews, were places which had been thought of as suitable to visit. Members desirous of using the holiday in the manner proposed should meet in the Council room on Tuesday evenings, the 7th and 14th instant, to make arrangements or otherwise signify their wish to join a party, the results of the day's work to be shown at the annual display in November.

Mr. TURNBULL then proceeded to give a description of the process by which stripping film negatives were obtained, and exhibited to the members a number of films, and his manner of detaching them from their paper and glass supports.

Mr. W. BASHFORD referred to the stripped eburneum films of twenty years ago, and how long a good idea sometimes had to wait before its merits were generally recognised and turned to practical account.

Mr. JAMES McGLASHAN remarked that care was needed in drying the film before removal, so as to secure the stage at which stripping was easy.

Mr. J. Wardale exhibited a new shutter release, which consisted in a small brass ball being propelled pneumatically in a short tube and caused to strike the trigger of the shutter, any shock being manifested after the exposure was made.

Grimstone's patent shutter for working between the lenses was exhibited by Mr. JAMESON, who spoke highly of its merits as a portable and ingenious piece of apparatus.

The ordinary meetings are suspended during July, August, and September.

Correspondence.

Correspondents should never write on both sides of the paper.

THE PHOTOGRAPHIC SOCIETY AND MEDALS.

To the EDITORS.

GENTLEMEN,—I have heard a rumour that the Council of the Photographic Society of Great Britain has under consideration the desirability of withdrawing the medals which have done so much to make the exhibition a success. Their decision is only postponed, I hear, that the feeling of the members of the Society may be obtained. How they intend to get the information I have no means of knowing, but, as a contribution to the subject, I have taken the trouble to make some inquiries, and send you a dozen of the replies I have received.

No. 1 writes:—"Quite a fatal mistake. Few of the leading photographers have anything to gain by exhibiting except honour. They will not care to go to the trouble and expense of preparing pictures for exhibition if they have nothing to hope for. There are already too many exhibitions to make anybody but the youngest amateurs eager to send to any particular one."

No. 2 says:—"You will have to send your Secretary into the highways and byways to fetch in the lame, the halt, and the blind, for the guests accustomed to honour won't appear."

No. 3. "We live in degenerate days. Emulation used to help a man to do his best. Perhaps, however, all really do their best, but don't want others to take the reward of doing better. Rank Socialism!"

No. 4. "Another robbery of the country members. The chance of the medals was all they had for their subscriptions, except the *Journal*, with three weeks' old news."

No. 5, who I expected would strongly object to the withdrawal, unexpectedly says:—"I don't care; it will suit me. It has been my modest ambition to have the largest collection of medals in the world, and I have got it. This, of course, will continue if others have no chance of levelling up."

No. 6. "Don't give up medals, but rule a certain number of regular medal takers out of competition, so as to give the second line a chance." This man belonged to what may be called the second line, and wanted

to get to the top of the tree by cutting away the upper branches, and making a fictitious summit. I suggested that the tree should be cut down to the stump to give that a chance, but he wouldn't see it. This correspondent also recommends that all the best pictures should be skied so as to give the general exhibits a chance. He also says something about removing the Queen, the Lords and the Commons, but politics are not to our purpose.

No. 7 airs his classiness:—"Metiri se quemque suo modulo ac pede verum est. Some people know themselves, and can never hope to win a medal, and object to have this pointed out."

No. 8. "Medals ought to encourage photographers, but if they are given as at our late exhibition—two each to the Hon. Treasurer and Hon. Secretary for very inferior work, and, in two cases, without competition—I should vote for their abolition. It will take years of good management to restore confidence in our Society."

No. 9. "Medals have made me a better photographer than I should have been. I have not won many, but the effort to win has been of incalculable service."

No. 10. "There was a time when the honour of exhibiting was enough, but that is passed, and pictures done for the honour of the art will cease to be produced if not encouraged by the hope of medals or similar rewards showing the approbation of fellow photographers of good work. But not, however, with diplomas for medals, as at Edinburgh last year. That was too ingenious a method of substituting paper for gold and silver."

No. 11. "Suicide! Leave out a dozen or twenty of the pictures usually medalled, and your exhibition would be no more worth a visit than those in Bond-street. Who cares to go over a thousand ordinary photographs with nothing to break the monotony?"

No. 12. "The suppression of medals would save me a lot of useless expense. I should never exhibit."—I am, yours, &c.,

AN EXHIBITOR.

PHOTOGRAPHING LIGHTNING.

To the EDITORS.

GENTLEMEN,—May I beg to call your attention to the enclosed circular which the Council of the Royal Meteorological Society have just issued to all the Photographic Societies and Clubs of Great Britain, in case you should think it worthy of some notice in your editorial columns.

The Council believe that photography may settle several points connected with the discharge of lightning, about which physicists differ very much, and hope that they may be able to enlist workers in this field of research.

The Council have also inserted advertisements in the leading photographic journals, so as to leave no stone unturned in their endeavours to obtain the information they want.—I am, yours, &c.,

WILLIAM MARRIOTT, Assistant Secretary.

"The Council of the Royal Meteorological Society are desirous of obtaining Photographs of Flashes of Lightning, as they believe that a great deal of research on this subject can only be pursued by means of the Camera.

"The Council would esteem it a great favour if you, or the Institution which you represent, could give them any assistance in this matter, either—1. By sending them copies of any Photographs of Flashes of Lightning that may have been already taken; 2. By endeavouring to procure them yourself, or to interest others in the work.

"It may be well perhaps to mention that the Photography of Lightning does not present any particular difficulties. If a rapid plate and an ordinary rapid doublet with full aperture be left uncovered at night during a Thunderstorm for a short time, Flashes of Lightning will, after development, be found in some cases to have impressed themselves upon the plate. The only difficulty is the uncertainty whether any particular flash will happen to have been in the field of view.

"The Council hope that now the Thunderstorm season is approaching, many Photographers may be found willing to take up this interesting branch of their art."

PRESERVATION OF FERROUS SULPHATE.

To the EDITORS.

GENTLEMEN,—I notice in the current number of the *Journal* a paper by Mr. Kenyon detailing an elaborate system for the preservation of ferrous sulphate solution. Is all this precaution necessary? I think not.

At one time, under the impression that a solution of this salt rapidly deteriorated, I adopted all manner of precautions, but found them troublesome, especially with rubber tubing and pinchcocks, for I found my tubing became covered with crystals of ferrous sulphate however tight the cock appeared to pinch. I find no difficulty in getting the solution to keep almost any length of time provided it is well corked. I always use the granulated sulphate of the Pharmacopoeia and do not make up any large quantity at a time. A small one suffices, as I am in the habit of using my developing (mixed) solution over and over again. After using I bottle it up, add a minute quantity of citric acid, and expose to sunlight, after the manner recommended by Mr. Hepworth in his little book on photo-

graphy, and to me it appears an old solution works even better than a fresh one; I may be wrong, but this my impression.

I enclose for your inspection a print on Fry's paper developed with a solution mixed upwards of a fortnight ago. I developed another one on Eastman's paper with the same solution directly after, with equal results. —I am, yours, &c., J. G. BRADEN, M.R.C.S.

Castle-place, Lewes, June 6, 1887.

[The enclosed print is very brilliant, and the blacks are singularly beautiful.—EDS.]

NEW PATENTED INVENTIONS WHICH ARE NOT NEW: CAMERA BACKS.

To the Editors.

GENTLEMEN,—In the issue of the 27th May of THE BRITISH JOURNAL OF PHOTOGRAPHY, you insert a notice of a changing back patented by Mr. A. S. Newman.

In his description of it he says:—"For this purpose I construct the changing box, holding any suitable number of plates, with two slits or apertures at the top of the box, one at the back and the other at the front. Over these slits a hood or covering is mounted of sufficient size to freely contain a plate, this hood or covering being formed of any flexible light-tight material (or it may be a bellows), and is securely fixed on the box," &c.

He then goes on to show how the exposed plate is to be raised through the front slot, and transferred to the back of the other plates by passing it through the back slot, and he describes a cranked lever and other means for raising the plate in the first instance.

To-day's JOURNAL brings Mr. Procter on the scene as a claimant of the idea, and I see by his letter that he used a changing arrangement very similar in the spring of 1885, and I note your remark at the foot of his letter to the effect that ingenious photographers would do well to send an account of their inventions to the journals.

I was the ingenious photographer who invented the method of changing plates, and I did publish an account of my invention in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, with a diagram, which any one may see by referring to the 1885 ALMANAC, page 140, under the title, *A New Departure in Dark Slides*. The account of my invention was sent to you in November, 1884, but it was invented, and I can prove it, in both single and double forms two years previously.

Mr. Newman's patent refers to a single back, but in my contribution I described a double back. It was, however, perfectly plain that the arrangement applied to both single and double backs, and, indeed, it was applied in the single form (with a fixed bag) first, like the ordinary single wet plate slide, but thicker. Seeing, however, that there would be less changing required by the double method (as by it a dozen plates or films can be changed in only five operations, the plates being in pairs back to back), I described that method in the ALMANAC. There were only two kinds of slides existing, the single and the double, at the time I was writing, and my title, *A New Departure in Dark Slides*, included both.

A member of the Club and of the Photographic Society of Great Britain, Mr. J. A. Harrison, knew of my invention long before it was published.

As to the two methods of changing, single or double, there are advantages in each. I think the double the most convenient. The plates in metal carriers take up less room by being two in a carrier, back to back, with a piece of thin black card between them, whereas in the single arrangement each plate needs a carrier and partition, making a difference in weight and bulk.

Having published my invention in the ALMANAC, I claim precedence over both Mr. Newman and Mr. Procter, and without attributing *mala fides* to either of them, it is singular that their inventions should crop up so soon after publication of mine.—I am, yours, &c.,

G. V. J. POIRIN.

2, Eardley-villas, Eardley-road, Streatham, S.W., June 3, 1887.

PHOTO-MICROGRAPHIC APPARATUS.

To the Editors.

GENTLEMEN,—Replying to "Procella's" letter on this subject in your last issue, I may say that in taking up this most absorbingly interesting branch of photography the necessity of perfect registration between the focussing screen and the sensitive film was at once apparent. To obtain this I use a single dark slide, having a carrier into which a loose focussing screen is fitted. The screen, after focussing, is replaced by the sensitive plate, which, occupying exactly the same plane, ensures perfect register.

Photo-micrography is now beginning to receive that attention to which its usefulness and importance well entitles it, and I quite agree with your correspondent that matters of detail, although small in themselves, cannot be too widely ventilated for the benefit of those who make photo-micrography one of their studies.—I am, yours, &c.,

Walthamstow.

J. J. BRIGGSNAW.

To the Editors.

GENTLEMEN,—I should like, with your permission, to make a remark on one point raised in the letter of "Procella" in your last issue. He

finds fault with the metal slides advocated by Mr. Nelson for use in photo-micrography, on account of the want of mathematical coincidence between the position of the sensitive film and that of the focussing screen, upon the absolute necessity of which he lays the greatest stress. Having given considerable attention to this very point, I venture to disagree entirely with the conclusions of "Procella."

The conditions involved in photo-micrography are exactly the reverse of those existing in photography—the former deals with a picture produced by divergent rays, the latter with one produced by convergent rays; in fact, photo-micrography is exactly like enlarging, and every one who has worked at the latter knows that in enlarging to any great extent a difference of position such as would be fatal to success in direct photography becomes inappreciable.

I have no hesitation in saying that with a distance of four feet between the eye-piece and the screen, a variation in position of half an inch of the plate would scarcely be perceptible in the negative, except by alteration of size.

With reference to the use of the eye-piece, "Procella" overlooks the fact that the corrections of objectives are made with a view to their being used in combination with eye-pieces, so that many objectives will not do their best without them; personally, I find that the convenience in working afforded by their use far outweighs any theoretical objections such as those advanced by "Procella."—I am, yours, &c.,

363, Old Kent-road, S.E., June 6, 1887.

EDWARD C. BOUSFIELD.

To the Editors.

GENTLEMEN,—Since you published, more than two years ago, my method of making photo-micrographs, I have been making numerous experiments in order to improve the results. In "Procella's" letter in your edition of the 3rd instant, I notice that he has never used an eye-piece for photo-micrography. It is probably a matter of opinion whether the eye-piece should be used or not, excellent negatives being produced by both methods. For my own work, which is chiefly pathological, anatomical specimens, and bacteria, I invariably use the eye-piece; and though for experiment I have frequently taken the same object without eye-piece, I do not hesitate in saying that in my hands the negative taken with the eye-piece is far superior to the other. I may have been more fortunate than some in my choice of oculars and objectives, but I have only once had to discard an objective for non-correction of visual and chemical foci.

In case it might be of use, I subjoin a complete list of the lenses I use for microscope photography:—

Eye-pieces.—Zeiss' Nos. 1, 2, 3, and the new series, No. 18, 10 mm.

Objectives.—Wray's 3 in. Zeiss' a*, A, DD., and one of the new glass apochromatics marked 16.0 mm., apert. 0.30. Leitz, homogeneous immersion 1/2.

I have tried Zeiss' new projection eye-piece, but can find no advantage in using it. His apochromatic series are perfect, and give a great "depth of focus." I have experimented on isochromatic plates, and think they will be useful, especially for double stained bacteria, though not necessary when vesuvin is used as a stain.—I am, yours, &c., J. COCKBURN.

Greyerook, St. Boswells, N.B., June 5, 1887.

To the Editors.

GENTLEMEN,—Referring to "Procella's" letter in your last issue, may I say that my experience differs somewhat from that of your correspondent? Accurate focussing is undoubtedly essential, but its attainment depends much more upon the distance observed between the object and the lens than the distance between the lens and the focussing screen or the sensitive plate, upon which the image is projected in the same manner as upon the screen of an optical lantern, the object itself being but a few inches from the lens, while the image is projected to a distance of many feet, and a considerable latitude in the position of the screen, after focussing, is allowable both in the case of the lantern and in that of the photo-microscope.

"Procella" might "dare" to try the metal slides in the photo-micrographic camera and be a gainer by the experience, as I became after daring against advice to try microscopic lenses not specially corrected for photography, and warranted not to work "true to focus," but they worked true to focus nevertheless. If, however, "Procella" insists that the focussing screen and the sensitive plate shall register accurately, then the metal slides (which I assume to be those of Tylar's make) are admirably suited for the purpose, as they separate into two parts, either of which can be used as a frame for the focussing screen, which may be held in position by two small spring clips, and after focussing the object it is not only possible but easy "to remove the screen from the frame and substitute the sensitive plate for it." I have been familiar with the working of these slides for a year or more, and now use no other kind.—I am, yours, &c.,

JOHN EDMONDS, President of the Birmingham

Hockley, Birmingham.

Microscopists' and Naturalists' Union.

VALUATION OF GOOD-WILL.

To the Editors.

GENTLEMEN,—I note your suggestions on this matter. I should think these bargains are generally made as you would buy a horse, by a rough

estimate, but if a proper systematic valuation is to be made, I would advise that an experienced photographer be asked to report (1), Upon the character of the locality and the surrounding population; (2), The suitability of the premises to the business; (3), To value the apparatus, or movable plant, and which could be sold by auction when done with; (4), The number and quality of the negatives; (5), To give his opinion as to the probable yearly return to be got from (a) the business; (b), the stock of negatives.

Having by these statistics and evidence arrived at the probable annual profit for a given term, I would say, What is the present value of an income of £— for — years at 10 per cent., which is to cover redemption of capital?

As an amateur, I have no idea of the value of such profits, but in the case of mines, where the risk is great, it is usual to take fourteen per cent. to redeem capital and fair interest, in the length of time the lease or supply of minerals permits.

To the above sum may be added the present value of the auction price to be realised by the plant at the end of the term, but this would be a very small sum. These present values may be either calculated or got from tables, and any present capital required beyond the mere price necessary to conduct the business should be deducted.

May I add a word on the proprietorship of the negative? When a dozen portraits of any size are ordered, the sitter is seldom, I believe, able to prove that there was a negative. By general knowledge he may be aware that he cannot be photographed without one, but he never sees it, unless by special goodwill of the operator, and if he gets his dozen cabinets that is all he asked for, and all that was promised him, or that he can prove is in existence.—I am, yours, &c.,
A. L. STEVENSON.

Durham, June 6, 1887.

COAL GAS AND FUMING PRINTING PAPER.

To the Editors.

GENTLEMEN,—Let me supplement your remarks on the use of coal gas. You mention that there are three dials visible. There is, however, another above these which is useful, not only to indicate leakage but also to measure the quantity of gas consumed per hour by any burner. On the smaller meters, such as are usually found in moderate sized houses, the hand moves once round for each foot that passes through (or for each two or three feet in larger meters as marked on the dial). It is thus easy by watching it for only ten minutes or so (each foot being divided into quarters) to calculate how much gas is being consumed per hour. I have tested all my stoves and burners in this way.

There is another matter to which you have scarcely alluded. This is the great excess of pressure, beyond what is desirable for economical consumption, which is generally given by the companies. For most purposes a pressure of less than one inch of water is ample, but three or four inches is nothing unusual, and in such a case the waste of gas is considerable. It may be remedied in two ways, either by small regulators on each burner, or one large one on the main just outside the meter. I use the latter, but as it is occasionally useful to have the full pressure for furnace work and other purposes, there is a bye-pass with tap, which allows the gas to pass, when required, without going through the regulator. N.B.—There are many so-called regulating burners which are humbugs.

In the same number your correspondent, W. K. Burton, mentions that the Americans dry their albumenised paper after silvering over a row of Bunsen burners without any ill effect. I can confirm this. It has been my practice for many years when only a few sheets are required. If there are many to do, I prefer drying over hot water pipes, but it would be too much time and trouble to heat the furnace (it is a gas furnace for the sake of cleanliness and simplicity) for only a dozen sheets or so. On only one occasion have I met with an accident, when the whole batch was sulphurated. [Editor—Query sulphurised.] I complained at the works, and they admitted that there was something out of order on that day.

Mr. Burton also remarks on the universal practice in America of fuming the paper. I have tried this over and over again as it has periodically cropped up in the journals, and my verdict is that it is an advantage with some samples of paper. I have had a ream now and then that would not work satisfactorily without fuming, and was all right with it, but with the paper I am in the habit of using, which is prepared to my special order, with from eight to twelve grains chloride of ammonium to the ounce—a much larger quantity I think than is used for commercial papers—fuming is no advantage whatever. The prints certainly look richer on taking them out of the frames, but there is no difference in the finished result.

My experience is entirely with Saxe paper and landscape work. It is possible that with other paper and for portraits there may be a difference.—I am, yours, &c.,
RUSSELL SEDGFIELD.

Norbiton, June 5, 1887.

DEVELOPMENT OF GELATINE PLATES WITH HOT WATER.

To the Editors.

GENTLEMEN,—In the paper on *Odds-and-ends*, by Mr. Heywood, in your last JOURNAL, he asks the question, "How a plate would be affected in development by hot water?"

I have during the winter used hot water for developing, and found it excellent both for ordinary negatives and transparencies on lantern plates. I consider I get a better tone (warmer) by the hot water.

I think if Mr. Heywood had used hot water in the development of the plates exposed in Norway they would not have frilled. In my experience hot water prevents frilling, and makes development much quicker. In instantaneous work it would be a great advantage, as the plate would develop sooner, and there would be less danger of fogging.—I am, yours, &c.,
EDWARD WOODWARD.

Upton, Macclesfield, June 4, 1887.

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—I am a lady amateur. I have had my portrait taken many times by professional photographers, but about the negative retained by them I gave no heed—indeed, the subject never entered my mind.

The correspondence, however, on this subject which has appeared in your columns has forced upon me the serious importance of the question, and I now ask myself, What right have photographers to retain the negatives of persons whom they have photographed, and for which they have been handsomely paid?

Criminals in our gaols are photographed and the negatives of them are kept, registered, labelled, and stored. Have ladies and gentlemen to be subjected to such criminal bondage, even against their will, by men whom they have employed and whom they have paid well for their work, by men of whom they know nothing further than their professional name? Have ladies and gentlemen, I again ask, to be subjected to such criminal treatment? to have their portrait negatives retained, registered, labelled, and stored for the profit of any man? Have ladies and gentlemen, to be freed from this criminal bondage, to pay blackmail?

I blush to think that any photographer who values his manhood would dare to uphold so monstrous a system.

This question is of sufficient importance for the daily press, and a good subject for our young men's debating societies.

The letters in your columns from the upholders of this wicked system are suicidal, and furnish the best possible evidence against it, and are levers for its correction.—I am, yours, &c.,
MILLIE.

Newcastle-upon-Tyne, June 4, 1887.

To the Editors.

GENTLEMEN,—Allow me to point out to "J. F., Newcastle-on-Tyne," that one man charges, and gets, for his first dozen of *cartes* four and sixpence, while another, presumably more gifted, charges, and gets, a guinea for his first dozen of same size photographs; so is it the negative image or the artistic and other abilities of the photographer that makes the difference in price?

Further, cannot able photographers, like other able artists or doctors, make their own terms with the public without being stigmatised as "J. F., Newcastle-on-Tyne" has done in the second paragraph of his extraordinary letter?

"J. F." might cogitate to some advantage over the "pound of flesh" T. Coan dangles before Mr. J. Dutton!—I am, yours, &c.,
Edinburgh.

USE AND WANT.

To the Editors.

GENTLEMEN,—Mr. T. Coan, in his letter which appeared in your JOURNAL of the 3rd instant, asked me, in reference to the proprietaryship of the impression on the film of the negative, "Supposing he or she desires to exercise the right to take away the said impression, how is it to be done?" Well, to use a vulgar expression in answer to a stupid question, "It cannot be did." But I said nothing about the right of the sitter to take it away; on the contrary, I said that custom had given the photographer the right to keep it.

Mr. T. Coan appears to think there can be no proprietaryship in anything that cannot be handled; in this, however, he is much mistaken. For example, the holder of the copyright of a book may put the MS. in his pocket, with a legal deed that secures the copyright to him; but the most valuable part of the property consists in the exclusive right of its production and sale—this he cannot put into his pocket. And again, when the book is set up in type to be printed it does not become the property of the printer, although the type used is his own; it still remains the property of the original owner, who, on the other hand, has no right to the type or the setting up without purchasing it. The analogy between this and the photographic negative is obvious and needs no comment.

Mr. Coan also mentions the "greedy photographer." Is it not rather the greedy amateur, who, not having the skill to make good portraits of his friends, wants the photographer to give up the negatives to enable him to print from them.

Perhaps, however, I should not take his letter seriously, as on reading it again I am inclined to think he only meant to make what Artemus Ward calls a "goak."—I am, yours, &c.,
J. DUTTON.

Bath, June 6, 1887.

To the Editors.

GENTLEMEN,—It is very interesting to your readers to know that your correspondent, "J. F.," of Newcastle-on-Tyne, considers that successful extortion cannot be eminently satisfactory to the profession. Why, however, does he draw the line at successful extortion? What has success or failure to do with it? "J. F." has left out of his letter what must certainly have been in his mind, namely, the familiar words, "God, I thank Thee that I am not as other men are, extortioners, unjust," &c. Leaving this, however, and returning to "use and wont," which I think must govern the question, I would remark that I am not a professional photographer, but remember more than twenty years ago buying of a professional photographer his negatives of a near relative of mine then lately deceased, and considered then, as I do still, that the transaction was a fair one, and that I was not the victim of "successful extortion."—I am, yours, &c.,

W. H. J.

To the Editors.

GENTLEMEN,—Having perused with considerable interest the correspondence in your valuable JOURNAL on the above subject, may I be allowed to solicit your opinion upon a question very much akin to what has been already treated in your columns? The circumstances of my case are as follows: I took a likeness of a certain person prominently connected with a popular movement, and presented it gratuitously to the party. Shortly afterwards, to my great astonishment, I saw a reprint of this identical photograph on the front page of a periodical issued by the fraternity, without my permission nor acknowledgment of authorship. Now, I am desirous to ascertain whether I have any power to make a claim for this glaring infringement of a right and pecuniary loss thus incurred, which should have been reserved by me and for me, or should at least be duly acknowledged as a copy from my production.—I am, yours, &c.,

Carnarvon, June 1, 1887.

JOSEPH KINSLEY.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Handsome black Newfoundland dog, will exchange for whole-plate wide-angle rectilinear lens by good maker.—Address, J. H. GORMAN, Dulverton.

Wanted, a wide-angle doublet lens, half-plate, in exchange for short-foens rapid C.D.-V. portrait lens by Shepherd.—Address, Mr. E. B. HOBSON, St. Paul's Vicarage, Halliwell, Bolton.

Wanted, in exchange for five backgrounds in good condition, a half-plate view camera with three double slides. Photographs sent. Or exchange in backgrounds.—Address, T. S. DAVIS, 4, Silver-street, Halifax.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

George Watmough Webster, 5, Eversley-park, Liverpool-road, Chester.—Eight views of Eaton Hall.

SIMMONDS.—Apply to Mr. Gotz, 19, Buckingham-street, Strand.

J. E. HOLMES.—Messrs. Marion & Co. supply the brass rims for mounting photographs; so does Mr. J. Fallowfield.

POSINO.—There is no work published on the subject. Your best plan will be to study the best work by our leading photographers.

ALONZO.—Brown-hard varnish is preferable to white-hard as a protective of negatives. The quantity of spirit added in either case is about the same.

Z. A.—For rapidity of action nothing surpasses the portrait combination; but, in proportion to its focal length, its covering powers are somewhat circumscribed as compared with other forms of lenses.

F. FREEMAN.—There is no photographic directory published. Kelly's *Chemists' and Druggists' Directory* contains the names of most professional photographers. This is the nearest approach to a directory of photographers.

LEX.—So many roll holders and analogous contrivances have from time to time since the earliest days of photography been described. If you refer to the annual lists of patents published in the *ALMANACS* from year to year you will find what has been patented.

W. A. C.—The markings on the plates are due to the manufacture and not to the development. The markings are known by many as "snail marks," and there is no method of getting rid of them when they exist. Sometimes, however, they do not show so strongly in the finished negative as their appearance on the plate would lead one to imagine.

D. MCGREGOR.—There are several methods of making opal enlargements. The simplest method is to make them direct on gelatino-bromide plates, such as are supplied commercially for the purpose. The makers supply a formula for the development. Opal enlargements are also made by the carbon process and by the powder process; sometimes, though rarely now, they are made on wet collodion.

E. D. writes: "The other day after I had toned and fixed a lot of prints I put them in a large bath to soak for the night; in the morning, on looking at them, I found that nearly all of them had blistered more or less. As this is my first experience of blistering, I am writing to ask you to be good enough to tell me the cause and remedy."—From what our correspondent says, we imagine that the blisters were not apparent overnight. If they were not they must have been caused by the long soaking. Usually blisters make their appearance either in the fixing bath or in the first washing waters. The remedy in our correspondent's case would be to effect the washing in a shorter period.

J. K. B. says: "I should be glad if you will answer me the following queries in respect to the working of a burnisher:—1. Ought the prints, after mounting, to be perfectly dry before passing through the burnisher?—2. If they must be dry, is it necessary to put any soap or other lubricant on the faces of the prints?—3. Ought the pressure to be heavy—say as heavy as when using an ordinary rolling press?—4. To about what temperature ought the tool to be heated?—5. How many times ought the print to be passed through the burnisher?"—In reply: 1. The prints should be perfectly dry before burnishing. 2. The prints should be lubricated. 3. About the same. 4. The "tool" should be made tolerably hot, but not sufficiently so to scorch the prints. 5. Until the requisite polish is obtained. This will depend to some extent upon the pressure applied.

H. W. PHILLIPS writes: "I. Will you kindly give me, in your 'Answers to Correspondents,' a formula for making and method of using the boracic acid toning bath?—2. And can you relieve me of a difficulty I have with my negative varnish? I have made some with methylated spirit and white-hard spirit varnish, but no matter how much I dry the negatives after varnishing they are always tacky. If you can give me a remedy for this I shall feel deeply obliged."—1. By "the boracic acid toning bath" we presume our correspondent means the borax toning bath; if so, the proportions are from half a drachm to forty grains of borax to each grain of gold in about eight ounces of water. 2. Evidently an unsuitable sample of white-hard varnish has been used. If the white-hard varnish were of the ordinary kind no difficulty would be experienced, and it would dry perfectly hard on the negatives. Our correspondent should get a sample from another source and try again.

A. S. asks: "1. Will you kindly tell me what objection, if any, there is to using paper negatives for portrait work? Would there be distortion?—2. Also if you will answer the following:—I have commenced saving wastes; I mix everything together—fixings, paper, and gold baths when they go bad. I use salt, but the water is still very black, caused principally by the discolouration by fixing plates in the hypo. Will chloride of zinc do to throw down the metals?"—In reply: 1. There will be very little distortion provided the paper negatives are not attached to a ridged surface whilst they are wet. The Eastman Company are now supplying a paper for negatives in which this trouble is reduced to a minimum. 2. If all the baths have been mixed together either salt or chloride of zinc is useless as a precipitant; sulphide of potassium (liver of sulphur) must be employed. It is better to keep the different wastes separate and treat them separately—precipitating the gold from the toning baths with sulphate of iron, the silver from the washing waters with salt, and that from the fixing baths with sulphide of potassium.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—On Saturday, June 11, there will be an excursion to Chislehurst. The train leaves Cannon-street at twenty-five minutes past two p.m.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, June 15, 1887, will be on *Backgrounds*. Saturday outing at Gravesend. Train from Fenchurch-street at eight minutes past two.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The last ordinary meeting of the present session of this Society will be held on Tuesday next, June 14, at eight p.m., at the Gallery, 5A, Pall Mall East, when a paper On *Photomicrography and its Value in Biological Research* will be read by Mr. Edgar W. Crookshank.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1415. Vol. XXXIV.—JUNE 17, 1887.

PERCENTAGE SOLUTIONS AND WEIGHTS AND MEASURES.

LAST week we promised to make a few observations on the subject of the mixing of percentage solutions, a topic with which questions of weights and measures are inextricably interwoven. Our attention was drawn to the subject by a number of letters in our contemporary, the *English Mechanic*, in reply to a querist who asked the meaning of the expression a "ten per cent. solution;" he had been told to take a "ten per cent. solution of chrome alum," and he asked, "Does this mean 10 ounces alum in 100 ounces of water, or 10 drachms in 100 drachms, or 10 grains in 100 grains?" The same question, in other forms, is doubtlessly being constantly put by other experimenters; repeatedly have we ourselves been called upon for an explanation. As we stated last week this querist was replied to by no fewer than six correspondents, which number included the names of at least one well-known authority, yet with one exception all made such erroneous statements in their replies as will form an excellent text whereon to expound this most simple, yet evidently confusing matter.

The first reply is vague; the second says, "A ten per cent. solution is one to ten." Wrong. The third is also vague at the outset and soon gets hopelessly wrong and at sea—"10 grains alum in 1 ounce water means 10 grains in 480!" The fourth is all wrong; he says, "If you take 10 parts water to 1 part chromic alum by weight," &c. He fails to comprehend the point. Number five says, "There is nothing vague about a ten per cent. solution of chrome alum. It means 10 parts of alum in 100 parts of water." This is evidently wrong, though the latter part of the letter shows a glimmering of the truth. Finally, the last letter states that in "photographic formulæ apothecaries' weight is always implied unless otherwise specified," a statement which is clearly erroneous, while still more glaringly so is it to say, as the writer does, that 10 drachms in 100 drachms is the same as 10 ounces in 100 ounces.

In trying to arrive at order out of this chaos of explanation, evidently typical of the state of mind of a large number of people, let us first explain what a ten per cent. solution does mean. It cannot be termed a strictly scientific expression; but by common usage it means, when applied to a solid dissolved in a liquid, a solution containing one-tenth of its weight of the particular solid. When applied to a mixture of two liquids it is usually understood to mean a liquid which contains a tenth of its volume of the specified liquid.

Thus a quarter of an ounce of a ten per cent. solution of chrome alum would mean a liquid which contained the tenth part of one hundred and nine and three-eighths grains of chrome alum. A pint of a ten per cent. solution of alcohol in water

would mean a solution containing two "fluid ounces" of alcohol.

Now the confusion of terms makes its appearance at this stage. Photographic formulæ, except for a few nice calculations, such, for example, as those needed in emulsion making and a few other directions, do not call for very exact measurements, as is instanced by the only recently forsaken "drop and pinch" formulæ for development; hence a somewhat slipshod mode of description is liable to be adopted. In practice no great harm perhaps is done, but the moment that exactitude of terms is asked for it is seen by our quotations how difficult it is to obtain it.

We have no purpose at this stage to enter into a discussion of the large question of the advantages and disadvantages of decimal *versus* other systems of weights and measures; we must take the British system as we find it, and endeavour to explain its apparent anomalies, though, once understood, they are simple and easy of application.

The unit of our system is the grain; upon it all other dimensions are founded. Thus there are four hundred and thirty-seven and a half of these grains to make the ounce of commerce, which only have photographers anything to do with. The troy ounce containing four hundred and eighty grains only refers to the precious metals and precious stones. Nitrate of silver is sold by the commercial (technically called avoirdupois) ounce. From this ounce we get the pound weight, which is equal to sixteen ounces. Confusion begins to grow interestingly intricate here. Every one knows there is a troy pound and an avoirdupois pound, each having its own number of ounces, also varying in weight as described; but if the grains figures only were remembered no difficulty need arise. The troy pound has five thousand seven hundred and sixty grains, the avoirdupois pound seven thousand grains—all grains it is understood being alike, whatever denomination they are connected with.

Perhaps if this were the only difficulty the true figures would soon be committed to memory, but, unfortunately, the capacity-measures tend in the opposite direction. The imperial gallon is a measure of a space which, when completely filled with water, would hold exactly ten pounds weight, or one hundred and sixty ounces. The one hundred and sixtieth part of a gallon, therefore, is a "fluid ounce;" but as a fluid ounce of water is equal to a weighed ounce, the first half of the word is usually dropped, a course which often leads to misconception when fluids heavier or lighter than water are in question. But the most unfortunate confusion of all consists in the divisions of the ounce. We have recalled the respective weights of the troy and the avoirdupois ounce, and here it may be mentioned that the ounce formerly used by apothecaries and by the chemist

and druggist, contained the same number of grains as the troy ounce—four hundred and eighty; hence, whenever the division of the fluid ounce into four hundred and eighty minims was called to mind, the majority of those referring to these divisions jumped to the conclusion that the minim and the grain were identical. This, however, it will be plainly seen they are not, for a minim of water is the four hundred and eightieth part of an ounce containing, not four hundred and eighty grains, but four hundred and thirty-seven and a half grains. Our readers who are not quite familiar with this point would do well to think it well over; they are not likely to forget it again. An ounce weight and an ounce measure of water (at suitable temperature and atmospheric pressure) are identical, and either contains four hundred and eighty minims or four hundred and thirty-seven and a half grains of water.

Let us in conclusion go back to the percentage question. If an ounce of chrome alum be dissolved in a small quantity of water, and, next, the solution made up in bulk to measure half a pint, that is, ten "fluid ounces," then every fluid ounce will contain a tenth of an ounce weight of chrome alum, but a fluid drachm will not contain a tenth of a drachm of alum; for if the latter term be employed at all (it was omitted over twenty years ago in the *British Pharmacopœia*) it means the eighth part of the apothecaries' ounce of four hundred and eighty grains. But this term should be entirely discarded and thus one form of confusion be avoided. We cannot but think the retention in our legal weights and measures of terms of similar name but different signification most unfortunate. It is the true cause of all this confusion.

PHOTOGRAPHING FLOWERS.

THERE remains little to be said beyond what has already appeared in previous articles on the general behaviour of orthochromatic plates in connection with their employment for flower subjects. Naturally with a class of objects exhibiting colour effects and combinations of the utmost variety and brilliance, these plates might be expected to prove themselves of the greatest utility, but it must be confessed that the actual results obtained are at first somewhat disappointing. We say at first, because though working in the ordinary manner, that is, without the coloured screen, we fail to secure those startling effects of colour reversal claimed by many; still, on more careful examination of the comparative results produced upon orthochromatic and ordinary plates respectively, there is a distinct advantage on the side of the former, more especially with flowers of the particular colours affected by the orthochromatic treatment.

A very large proportion of the more ordinary and popular flowers are of these particular colours, purple, blue, yellow, and orange, in their various shades and combinations, and mingled with white and green; blossoms of these colours are not only better rendered photographically, but there is also, even without the coloured screen, a nearer approach to the accurate expression of their colour values to the eye. But the large variety of colours comprised under the various shades of red, scarlet, crimson, pink, &c., are, if anything, sufferers from the employment of orthochromatic plates, for while the sensitiveness of the film has been left intact, or perhaps even lowered for those colours and for white, the yellows and greens have had their active value considerably increased. Thus flowers of red tints are found to suffer, especially the lighter ones, in comparison with blue and yellow blossoms if such be in juxtaposition; but what is of greater importance, they suffer in a

still greater degree in the comparison with their own foliage, which is rendered proportionately much lighter. To take a familiar example, we will instance a bright scarlet geranium, which will be found to be rendered many shades darker in comparison with its foliage when taken upon an orthochromatic plate than when an ordinary gelatino-bromide or a wet plate is employed.

Many of the exquisitely varied blooms of show pelargoniums form extremely difficult subjects to render photographically, owing to the strong colour contrasts of their markings as distinguished from the contrast to the eye. Take, for instance, any of those species combining white and delicate pink with markings of deep carmine merging into dark velvety claret or maroon. To the eye the lighter tints are perfectly distinct in spite of their delicacy, as are also the darker ones from the sheer contrast of their colour brilliancy; but in the camera the first are rendered as almost unbroken white, the others a uniform black, or the closest approach to it, and the general result is a most unsatisfactory contrast between nearly pure black and white. With ordinary plates, especially with wet collodion, much may be done by modifying exposure and development to remedy this state of affairs, but when orthochromatic films are employed such treatment serves but to emphasise the peculiar effects resulting from the plates themselves.

But as has been said, orthochromatic plates have unmistakably some advantages if their use be judiciously applied. For instance, if we take simple yellow flowers such as the ranunculus, dandelion, daffodil, narcissus, marigold, or sunflower, the mere heightening of the sensitiveness to yellow brings about a better rendering of the subject independently of any "orthochromatic" effect, simply because the blossom—as well as the foliage—receives a better exposure. We had a striking example of this a few days ago in photographing a laburnum tree in full blossom. The result upon an ordinary plate was such that no one inspecting the picture would have imagined the tree was in flower, foliage and bloom being of one uniform depth of tint. Upon trying an orthochromatic plate, however, the blossom was readily distinguishable without giving any effect of "snowiness" to the tree. When we turn to flowers in which yellow is contrasted with white, blue, or purple, the effects are still more marked, and here the advantage is reaped of whatever orthochromatic effect is to be secured without the coloured screen. Take, as an example, the common field daisy, with its pure white or crimson tipped petals and yellow centre. Few would recognise it from its photograph on an ordinary plate, its dark centre giving it more the aspect of a dwarf sunflower. But the power of the orthochromatic plate suffices to soften the contrast, and, by bringing up the yellow, to give a more natural aspect to the rendering.

But it is of course when yellow is contrasted with blue or purple that the most marked difference accrues from the use of the colour prepared films, though even then it is only in cases of very violent chromatic contrast that a specially palpable distinction is apparent, such as would be recognised at a casual glance, and such as would be produced with the aid of the yellow screen. The pale blue of the forget-me-not contrasted with its delicate yellow "eye," forms an instance in which it is difficult to distinguish the results of ordinary and orthochromatic plates; but if we turn to the large class of pansies, in which rich golden yellows enter into combination with deep velvety purples, almost reaching black, we find that the stained plates give a decidedly more favourable rendering.

Blue, in conjunction with white, forms another combination in dealing with which orthochromatic plates prove useful, and no more striking example could be selected than the pretty convolvulus of the old fashioned garden.

Of flowers of these descriptions and colours there are a very large number of favourites both in the garden and the hot-house, and though we have confined ourselves to the more popular ones in our remarks, still the amateur who has the contents of a conservatory at his disposal as subjects for the camera will find innumerable instances where orthochromatic plates employed without the screen will help him, if they do not give the full degree of success he would desire. If the coloured screen with its disadvantages be adopted the results may in cases be better, but on the whole we do not consider the "game worth the candle."

Occasionally combinations including red tints are found to be benefited by using orthochromatic plates. For instance, we recently met with a flower of the marguerite class, having crimson or carmine petals and golden yellow centre. With ordinary plates the colours were rendered of perfectly uniform tint, but upon applying an orthochromatic plate the difference was very distinct, the centre being considerably the lighter. Whether it was the heightening of the sensitiveness to yellow, or the lowering of the red, that produced the result we cannot say, but most probably the latter. Another example shown to us by a friend last year consisted of a group of *Rhodanthe maculata* in which deep rose, yellow, and crimson, enter into combination. The orthochromatic rendering was decidedly the better of the two, the colours being more clearly defined, and this in spite of the fact that the rose and crimson are in juxtaposition.

Sufficient has been said to show to those who wish to make flower photography a hobby, that while we would recommend them to use orthochromatic plates for some subjects, we should not advise them to rely upon them in all instances, nor do we desire them to expect too much from such use. If the operator employ them judiciously and rest content with what assistance they are capable of rendering, he will not in the long run have cause to complain.

In a note to the *Photographische Mittheilungen*, E. Vogel, jun., states as the result of experiments made by him that he finds when isochromatic plates have been prepared by immersing ordinary plates in a bath of azalin they lose their sensitiveness to some extent, but by subsequently immersing them in a two per cent. solution of ammonia their sensitiveness is quite restored.

When in Manchester the other day, we learned that Mr. John Eastham, who was one of the early pioneers in photography in Manchester, is suffering from the distressing malady which goes by the name of aphasia. This most melancholy condition is characterised by an inability to employ suitable words for the expression of thought, so that though the faculty of speech remains, it fails to communicate the ideas of the affected person. The attack is often sudden, and frequently arises from embolism of the cerebral vessels. As Mr. Eastham is in very reduced circumstances, it is to be hoped that friends who knew him in his better days may be found willing to interest themselves on his behalf. Mr. Eastham is now living in Bradshaw-street, Higher Broughton.

The long continued action of moisture is generally looked upon as being most destructive to photographs. That it does have a deteriorating influence, under certain conditions, no one will deny. Under some circumstances, however, it would appear to be inert, if we may judge from some examples shown by Mr. Fred. Hollyer at the meeting of the Photographic Club last week. These pictures

—silver prints—had been kept damp for no less than five years, and appeared none the worse for the transaction. We learn that the prints were placed in blotting-paper to dry, but the parcel got mislaid, and was not found till quite recently—five years afterwards. It was then discovered in a damp portion of a dark room under a pile of other things, which had not been disturbed for years. When found the blotting-paper was moist, covered with mould, and smelt offensively. It could not be handled for rottenness. The prints were also mouldy on the backs, but the image was uninjured. After drying, and the mould being wiped off, the prints seemed none the worse for being retained under such adverse conditions, except that the back of the paper was permanently stained by the mould. Mr. Hollyer drew the particular attention of the members to the fact that, during the time the prints were in the blotting book, they were protected from the action of the atmosphere. This, he considered, had a far more pernicious action on photographs than moisture pure and simple.

MANY professional photographers, both in London and in the provinces, are complaining loudly of the unfounded reports which have appeared in the non-scientific press, to the effect that a process of photographing in colours has been discovered is causing them considerable annoyance in their businesses. Clients, they say, refuse to believe that the report is incorrect because so much prominence has been given to it by some of the daily papers, and they refrain from having their portraits taken for the present unless they can be done by the newly discovered process. One would almost have imagined that the discovery of a method of taking photographs in natural colours had been heralded so often that, like the "cry of wolf," it would have no importance attached to it. Such does not appear to be the case. Perhaps, however, the association of a well-known photographer's name with it has had something to do with the credulity on the present occasion; usually it is some obscure foreign scientist who has made the "important discovery." Mr. Mayall has made no claim to "photography in natural colours," though it has been made for him by certain London papers, and reiterated in many provincial ones. In most instances the report remains uncorrected.

THE inconsistencies of some of the newspapers on the subject of the so-called colour photography have been most amusing. For example, the *Daily Telegraph*, a short time back, in a leading article on Mr. Mayall's (?) discovery, after speculating as to what will be the attitude of such men as Sir Frederick Leighton, Sir James Linton, Mr. James Whistler, and the societies they preside over, and making some remarks anent fast and fugitive pigments, adds, "If the naturally coloured portraits of which the perfected execution has been proclaimed will really 'wash'—that is to say, if their permanency can be proved by time—it is clear that ere long little short of a revolution must be expected, not only in portrait painting but in many other important branches of art." A few days later, when commenting on the Cellerier Syndicate's productions, our contemporary says: "It is needless in these days, when a scientific primer can be bought for one shilling, to point out the boastful absurdity and inherent nonsense of any pretensions to photograph colours directly. To do so would be to attempt to rival the exploits of those wise old gentlemen of Laputa whom Lemuel Gulliver discovered engaged in the process of extracting sunbeams from cucumbers." It is to be regretted that the editor did not invest a shilling before writing the first article, as it would, to an extent, have prevented the public from being misled, and saved many photographers some little annoyance. However, there is an amusing side to the question, and this the latter have enjoyed.

THE taste for matt surface pictures is undoubtedly on the increase, and will doubtless continue so, particularly if photographers give it encouragement. Most of the matt surface prints now produced are either by the platinotype or the gelatine process. One seldom nowadays meets with a print on what used to be known as "salted paper," and we question if many modern printers would know how to produce one. Whenever a matt surface print is now required, the usual practice is to sensitise a piece of ordinary albumenised paper on the back and to print on that. This is a clumsy expedient, and the

result obtained is far from satisfactory, as the image always has a flat and sunken-in appearance, very different from the plain prints of former times. Moreover, the picture is on the web side of the paper, which always gives it an unpleasant appearance. Plain salted paper used to be an article of commerce, and was kept by every stock dealer, but now we question if it can be obtained ready prepared. Perhaps plain salted paper would meet with a sale if it were forthcoming.

A CORRESPONDENT writes that M. Lambert, when over here some years ago demonstrating his processes, showed some, if not all, of his licensees a method of colouring carbon prints from the back similar to that recently described as a patented process. We believe he did, but the same thing was done by others long prior to the introduction of the Lambertype processes, and analogous methods of finishing carbon prints have been introduced since.

THE MANCHESTER EXHIBITION.

I.

TRUE to their instincts, the Manchester men seem to have got up their Jubilee Exhibition on a scale worthy of themselves and their great city. They appear to have been pervaded by a spirit similar to that by which they were actuated in 1857, when their smoky city was elevated into the position of being the most spoken-of place in the world. For it was then that Cottonopolis had reared an art palace and had gathered within its walls the art treasures of Europe. Where else could be seen under one roof, as we saw it in the June of the year mentioned, twenty-eight pieces of Raphael, thirty-five Murillo's, thirty Titian's, with an even greater plethora of the works of Rubens, Vandyck, Rembrandt, Teniers, Tintoretto, Leonardo de Vinci, Michael Angelo, and numerous other masters of the foreign school? When added to these were the innumerable home artists of former and contemporary times, including Reynolds, Hogarth, Gainsborough, Romney, Opie, West, Wilkie, Etty, Landseer, Leslie, Maclise, Faed, Gordon, Danby, and hosts of others who were represented by those works which are so familiar in the history of art, one is inclined to wonder not only at the boldness of the conception by which "cotton spinners and weavers" should aspire to making a collection such as was never before achieved, but at the astonishing success by which their efforts were crowned.

The spirit which animated these merchant princes thirty years ago evidently pervaded their successors, who have gathered together in nearly the same place and under more than one roof, large though they be, treasures of another class, yet which transcend in their influences on mankind that of the former period. Manchester is, and has good cause to be, proud of its Jubilee Exhibition.

But we started with an intention to speak of the Photographic Section of this singularly large and attractive exhibition. And first we would observe that it is noteworthy in this respect that it is "large and fine," notwithstanding the absence of the bait of medals, which proves so attractive and alluring to many. Of course there are some whose contributions are seldom far off from an exhibition when allured by the temptation of a possible medal award, but who in one like the present seem to prefer remaining absent. When will the time come when photographers, like painters, will exhibit their works solely for the love of the art and the honour that redounds to themselves, unmixed by the less worthy consideration of reward in the form of medals?

The Exhibition is very rich in what appertains to the history of photography. There is a *facsimile* of the earliest known sun picture, or heliotype, by Thomas Wedgwood, about 1791-3, kindly lent by B. J. Sayce. There are several Daguerreotypes of Daguerre, Faraday, Goddard, and others, taken in 1841 and the subsequent few years, together with Talbotype negatives and prints from them by various of the early artists, among them being the famous Edinburgh calotypist, D. O. Hill, who flourished in that capacity in 1843. There is a portrait of Sir John Herschel, which must possess great interest for all who are acquainted with the scientific labours of that eminent man in the earliest days of photography; and, almost better still, there is exhibited in one of the show-cases his famous letter to Mr.

Brothers, of Manchester, in which he described his discovery of the fixing powers of hyposulphite. This letter, we think, possesses so great a degree of value as a historical document that we here reproduce it:—

"Collingwood, October 29, 1864.

"SIR,—I think I may very fairly claim the discovery of the hyposulphites as fixing agents, as I believe I was the first to call the attention of chemists to that class of salts and their peculiar habitudes, especially in relation to the insoluble salts of silver.

"In my paper *On the Hyposulphurous Acid and its Compounds*, which bears date Jan. 8, 1819, and which appeared in Brewster and Jamieson's *Edinb. Phil. Journal*, 1819, occur these words:—

"One of the most singular characters of the hyposulphites is the property their solutions possess of dissolving muriate of silver and retaining it in considerable quantities in permanent solution." (p. 11.)

"*Hyposulphite of Potash*.—It dissolves muriate of silver, even when very dilute, with great readiness." (p. 19.)

"*Hyposulphite of Soda*.—* * * Muriate of silver newly precipitated dissolves in this salt when in a somewhat concentrated solution in large quantity, and almost as readily as sugar in water." (p. 19.)

"*Hyposulphite of Strontia*.—* * * Like the rest of the hyposulphites, it readily dissolves muriate of silver, and alcohol precipitates it as a sweet syrup." (p. 21.)

"*Hyposulphite of Silver*.—Muriate of silver newly precipitated is soluble in all liquid hyposulphites, and, as before observed, in that of soda with great ease and in large quantities. This solution is not accomplished without mutual decomposition, as its intense sweetness proves—a sweetness surpassing that of honey, and diffusing itself over the whole mouth and fauces, without any disagreeable or metallic flavour." (p. 27.)

"In a second paper on the same subject, which appeared in the same journal, vol. 1, p. 396 *et seq.*, it is shown (*inter alia*) that the affinity of this acid for silver is such that oxide of silver readily decomposes hyposulphite of soda and likewise the soda in a caustic state, 'the only instance, I believe, yet known of the direct displacement of a fixed alkali *via humidâ* by a metallic oxide.' (p. 397.)

"*Hyposulphite of Ammonia and Silver*.—Its sweetness is unmixed with any other flavour, and so intense as to cause a pain in the throat. * * * One grain communicates a perceptible sweetness to 30,000 grains of water." (p. 399.)

"In a third communication, dated November, 1819—'The habitudes of this acid with the oxide of mercury are not less singular than its relation to that of silver.' 'The red oxide is readily dissolved by * * * hyposulphite of soda, while the alkali is set at liberty in a caustic state,' &c., &c.

"The very remarkable facts above described, I have reason to believe, attracted a good deal of attention at the time, and thenceforward the ready solubility of silver salts, usually regarded as insoluble by the hyposulphites, was familiar to every chemist. It would not, therefore, be surprising if Daguerre tried it to *fix* his plates (*i.e.* to wash off the iodide coating); but I have been informed, though I cannot cite a printed authority for it, that at first he fixed with ammonia, or with a strong solution of common salt.

"For my own part, the use of the hyposulphites was to myself the readiest and most obvious means of procedure, and presented itself at once. My earliest experiments were made in January, 1839, and in my notebook I find:—

"Exp. 1012.—1839, Jan., 29. Experiments tried within the last few days' since hearing of Daguerre's secret, and also that Fox Talbot has got something of the same kind." [Here follow some trials of the relative sensitiveness of the nitrate, carbonate, acetate, and muriate of silver. I should observe that at that time I did not even know what kind of pictures Daguerre had produced. This process was not revealed till August, 1839.]

"Exp. 1013.—Daguerre's process: attempt to imitate. Requisites—1st, very susceptible paper; 2nd, very perfect camera; 3rd, means of arresting further action. Tried hyposulphite of soda to arrest the action of light by washing away all the chloride of silver or other silvering salt; succeeds perfectly. Papers half acted on, half guarded from the light by covering with pasteboard, were withdrawn from sunshine, sponged over with hyposulphite, then washed in pure water, dried, and again exposed. The darkened half remained dark, the white half white, after any exposure, as if they had been painted with sepia."

"Jan. 30, 1839.—Formed image of telescope with the aplanatic lens * * and placed in focus paper with carbonate of silver. An image was formed in white on a sepia-coloured ground * * which bore washing with hyposulphite of soda, and was then no longer alterable by light. Thus Daguerre's problem is so far solved," &c., &c.

"Exp. 1014.—Jan. 30, Tried transfer of print and copperplate engraved letters," &c., &c.

"The publication of Daguerre's process (according to Dr. Monckhoven, for I cannot at present refer to the original document) took place on the 19th August, 1839. My early experiments were printed in the notices of the proceedings of the Royal Society of March 14, 1839, in which occurs this passage in the abstract of a paper read to the Society:—

"Confining his attention in the present notice to the employment of chloride of silver, the author inquires into the method by which the blackened traces can be preserved, which may be effected, he observes, by the application of any liquid capable of dissolving and washing off the unchanged chloride, but leaving the reduced oxide of silver untouched. These conditions are best fulfilled by the liquid hyposulphites."

"Twenty-three specimens of photographs made by Sir J. Herschel accom-

pany his paper—one a sketch of his telescope at Slough, fixed from its image in a lens."

"This is the image above mentioned as having been taken on Jan. 30, 1839, and was, I believe, the first picture ever fixed for an optical image ever taken in this country—at least I have heard of none earlier.

"At the time of making these experiments, as already mentioned, I had no knowledge of M. Daguerre's process further than the mention of the existence of a process (a secret one) in a note from Admiral (then Captain) Beaufort some time about Jan. 23, 1839. Of course I used paper, not silver, and it was not a suggestion, but a regular and uniform practice, to use the hyposulphite; I never used anything else.—I am, sir, your obedient servant,
"J. F. W. HERSHEL."

Occupying a prominent position in one of the cases are examples of Léon Vidal's photochromes, or photographs printed in coloured pigments, which will be examined with all the greater interest that attempts are being made at the present time to introduce coloured photographs the pigments upon which are applied, altogether unlike Vidal's polychromes, by the more or less skilled hand of a colourist.

These polychromes are very bright and possess perfect gradation. Let it be understood that this is not a method of applying colour to an already existing photograph in monochrome, but of printing it in colours *ab initio*. The specimens now in Manchester form a portion of some which were brought before the notice of the British Association at their Bradford meeting in 1873, where an account of their mode of production was given by the present owner of them. The process was originally based upon the carbon or pigment printing process, but resembled in principle chromo-lithography. Every different tint shown in the picture implied a separate print, the colouring matter of which was set off or transferred to the sheet upon which the finished picture was finally impressed. As many negatives had to be employed as there were colours to be printed.

This was troublesome, but out of it was evolved a much simpler and better system, namely, one in which collotypic printing formed the means of production. The negatives are prepared as mentioned, that is, there must be as many negatives as there are colours to be produced, and from each negative must be stopped out every part that does not represent one special colour.

Suppose that the subject is a rose tree clad with foliage, and adorned with red flowers. The negatives are obtained by superposition from one original: all but the flowers, the trunk, and the leaves are then respectively stopped out in the separate negatives. Three printing "formes" or surfaces are now prepared, one for each of these negatives; the printing surface being of course gelatine, as adopted in the collotype process. The leaves are first printed, being inked with green. These will appear in all the beautiful delicacy and with all the structural detail visible in the original tree. When the requisite number—hundreds or thousands—of impressions has been printed, the printing surface is removed (one press only is now supposed to be employed), and a second "forme," representing the flowers, is inserted in the bed of the press. This is inked with a transparent red lithographic ink the colour of the flower, and the partially printed proofs are sent through the press a second time, care being taken to keep correct register. A third time the operation is repeated, so as to introduce the brown colour of the trunk and branches. If necessary, colours may be made to overlap.

What is here adduced as a means of printing flowers applies equally to that of landscapes, portraits, and indeed to everything that can be represented by photography.

We close the present article by saying that great praise is due to Mr. Brothers and his colleagues of the Manchester Photographic Society for the ability they have displayed in getting together such an excellent exhibition of photographs, both ancient and modern, a description of which we shall resume next week.

THE POTASH DEVELOPER.

THE season and the weather are with us now to remind photographers that ammonia is a nuisance, either as a developing agent or in any other capacity, and most operators will agree, at least while the present temperature lasts, that it should be banished the dark room altogether. It is not only that its escaping fumes are noxious to health, and that its extreme volatility renders it a very uncertain developer, but it is likely under extreme circumstances to prove really

dangerous, a fact of which I was disagreeably reminded a day or two since when, in moving a bottle of ammonia that had not been opened for some time, the stopper flew out and I was deluged with the contents, liquid as well as vapour, which narrowly escaped my eyes. The bottle had been closed in cool—more than probably, in *very cold*—weather, and after the recent sudden rise of temperature was ready to go off like a bombshell at any moment.

Then, again, the troubles that arise to the health from constant contact with ammonia vapour in a close space are at any time bad enough, but with the temperature at eighty odd and a flood of hot-looking red light coming into the room without any adequate counterbalancing supply of air to temper it, it is no wonder that the additional irritant effect of ammonia vapour on the system should produce headache, lassitude, and loss of appetite, to say nothing of the nasal catarrh it brings on at any time when the system is saturated with it.

From the purely photographic point of view, these objections may be regarded as merely sentimental; accidents to limb or health form no part of an operator's contract, he has to develop negatives. But the same volatility that causes the ammonia to distribute itself so lavishly about the place also causes it to escape from its solutions. If "H. P. R." has reason to complain of the developing uncertainties arising from incorrectly graduated measures as described in his recent letter, I think he, or any one else, would find he suffered infinitely more in the same direction during such weather as the present if the ammonia developer be used without making a fresh solution every few minutes.

For these and other reasons I have long discarded ammonia for all but experimental purposes, finding the carbonates of potash and soda far more reliable, free from smell, cheaper, and what is of the greatest importance, giving *at least* as good results as ammonia. Such, at least, I claim for potash, but I must confess to an absolute dislike to carbonate of soda, on account of the horrible yellow colour it imparts to the gelatine film—not to the image, but to the gelatine which holds it. It is a curious fact that, notwithstanding very many of those who constantly use carbonate of soda declare they are not troubled with the yellow stain, it always appears with me, notwithstanding the use of sulphite of soda, and quite irrespective of the make of plates. If by quick development and the free use of sulphite an uncoloured negative should result, the stain invariably appears on washing; in fact, it seems to be a case on a par with that of the Irishman who asserted that the water of his native village "washed the dhirt into yez."

On the other hand, it is alleged against carbonate of potash that it causes frilling where frilling would not otherwise appear; but my experience does not go to that length. I will admit that if a plate be weak—that is, will just bear ordinary treatment, but no liberties in the shape of forcing—potash will search out its weakness; but with the general run of commercial plates I do not think any difficulty need be experienced. If a plate frills with potash, it will not be found difficult to make it frill with ammonia, or even ferrous oxalate. But the remedy is easy, and if the plan be regularly adopted the difficulty need never appear. It is simply to use a strong solution of common salt between development and fixing as recommended some time ago in the JOURNAL.

I am not going to recommend any new formula, for the very good reason that I do not believe in them. A formula for developing is all very well as something to which to stick a man's name as a handle, but if the owner of the "handle" would also invent a formula for the production of images that require strictly uniform treatment, he would better deserve the distinction attaching to him, and would, at the same time, save himself an immensity of trouble in continually altering his formula, as appears to be the practice of such gentlemen with every fresh packet of plates they open.

If ten per cent. solutions of pyro and bromide and a more concentrated solution of alkali be kept, the operator is prepared to "tackle" any plate that ever left its maker's hands with the capacity of making a picture in it. I do not say those solutions would enable him to do much or anything with a square of glass and some spoilt emulsion, but if the plate has the capability of making a negative at all, they will, properly handled, bring as much—in quality, I mean—out of it as the maker's own "extra special" formula. That is the

only formula I recognise—solutions of known strength. Ten per cent. is a convenient strength for the two named, but the alkali is better stronger, so long as it is known that a definite quantity is contained in each drachm.

Before speaking of the strength of solution I employ, I should like to say a word or two regarding the kind of material employed. It is insisted by the author of at least one potash formula that the "pure" article must be used. The recommendation is very good in as far as it offers a better chance—without, however, ensuring—that a definite article is obtained and a solution of uniform strength. But it is not at all necessary, as the "commercial" article at eightpence per pound sold as "commercial purified," or "salts of tartar," is quite as good if only properly used. The only treatment it requires is to have it thoroughly dried before weighing, as it is extremely deliquescent, and being a cheap substance is not kept with any particular care in most retail shops. The pure article possesses the same characteristics, but owing to the greater care used in its storage is not likely to go so far wrong as the cheaper; still, it is always desirable to apply the drying treatment to it also. This is easily done by spreading it on a plate or dish, and leaving it for a sufficient time in a moderately hot oven.

If, however, the operator should hanker after purity he can have it at a cheap rate by adopting the following plan. Instead of buying "salts of tartar" let him ask for bicarbonate of potash, which can be obtained at any chemists or oil shop in the kingdom, and costs the same as the salts of tartar, namely, eightpence the pound—at least, it should at any respectable shop, though some chemists would perhaps charge eightpence an ounce for it if the purchaser looked as if he had as much money about him.

If the operator is chemist enough to perform the operation he should next "ignite" the bicarbonate; but presuming that he is not, let him transfer it to one of the common "block tin" baking dishes and place it in a good hot oven. This drives off the extra atom of carbonic acid, together with an atom of water, and leaves pure anhydrous carbonate of potash. The operation is complete when steam ceases to rise from the salt when stirred. Let it be weighed as soon as cool.

And now with regard to the strength of the solution. The solubility of the pure carbonate is very great, about an equal weight of water sufficing to dissolve it at ordinary temperatures, but so strong a solution would be inconvenient to use. Plates differ very greatly as regards the quantity of the salt they will stand or require, some developing well with as much as twenty grains to the ounce, others requiring only five. Twenty grains to the drachm of solution, or one hundred and sixty to the ounce, will therefore form a convenient strength, one drachm sufficing for one, two, or four ounces of developer as the plate may require.

For general everyday work, when a large stock of solution is made and kept ready for use, it is of course not necessary that the quantities should be weighed out exactly to a grain as in experimental work, a grain more or less in the ounce of developer being of absolutely no moment. We can, therefore, proceed, in quantity, in a more convenient manner than by weighing out exactly so many hundred grains, even if we have the weights at hand. Thus, a pound avoirdupois consists of 7000 grains, and forty fluid ounces of solution containing 160 grains to each ounce will require 6400 grains. If, then, we allow for a considerable quantity of moisture in the pound of salts of tartar as it comes from the oilshop, we may make it into forty ounces of solution, and be pretty certain that it will not be far off the strength of twenty grains to the drachm. If we are a little more particular, and dry the carbonate before dissolving, fifteen ounces to the quart will be very slightly over the mark.

If the bicarbonate be used it must be remembered that one pound of the acid salt represents but eleven ounces of the neutral carbonate, five ounces, all but a very minute fraction, being driven off in the shape of water and carbonic acid gas. If, then, one pound of bicarbonate be converted into carbonate as described, and dissolved to make *thirty* ounces of solution, each ounce will contain within one-twelfth of a grain over the required quantity.

I feel certain it would be to the interest of large establishments to make such stock solutions in quantities sufficient to last for some weeks. The materials are cheap enough and the quantity of solution

actually used is very small, so that in the concentrated state not much storage room would be required. The gain in uniformity of work from always using *the same* solution would soon be felt, for I scarcely think any photographic laboratories are likely to vary between their extremes of temperature sufficiently to alter the specific gravity of the solution to such an extent as to alter its developing power.

H. Y. E. COTESWORTH.

ON THINGS IN GENERAL.

DURING the early part of the year I was asked the question, "When shall we hear of photography in colours being invented?" "In all probability in a few months' time," I replied; "as, for the last quarter of a century it has been regularly discovered every two or three years, and it is now about time it was invented again." My prophecy came true sooner than I anticipated, and all honest photographers must feel almost ashamed of their profession to see the impudent way in which the public are being gulled by a few astute advertisers, who are now exploiting this ever green field of innocents. One would have thought that the experience of a few years ago would have served for almost two generations. My readers cannot fail to remember the inventor who managed to net some considerable sums of money from a credulous public which applied for shares in a company launched for working a photography-in-natural-colours plan. Then, as now, the daily papers, by their gorgeously worded articles, unsuspectingly lent their aid to the deception, and again is the same sorry game being played.

All these pseudo photography-in-colour processes come at a most inopportune time for the progress of true science, for we have once more among us, one might almost say, that talented worker in the theory of photography, Mr. Carey Lea, and I hail with enthusiasm the familiar and respected name, joining with Mr. Hanson, of Leeds, who wrote a week or two ago, in offering my sympathy in the painful cause of his long absence and in all good wishes for the future. Such workers in the cause of science are few and far between—we cannot afford to lose them; and every one will acclaim Mr. Carey Lea's return, especially accompanied, as he is, with such loads of good things in the shape of investigations in this most interesting field, the true photography in colours.

We seem likely to have a plethora of changing boxes for a while, and I join with the Editors in their suggestion to a correspondent who sends a box of his own resembling a recently patented instrument of the kind, that, whenever a really efficient improvement is devised, that a description should be published in these pages. There would be then no doubt about priority of publication, a very potent, yet disputable, factor in patent matters. But why changing boxes at all? A set of neat dark slides don't weigh much more, and are infinitely preferable. There are one or two really good changing boxes in the market, but defend me from the majority of them! I know of a photographer who possessed one such affair who went with a chosen few to the Isle of Man, on photographic pleasures bent. They all set to work upon a lovely view, but our friend of the box appeared rather dilatory. The rest of the party exposed their plates and prepared to retire. The changing box owner, however, was fixed: his plate would go neither in nor out. He coaxed it, tried first gentleness then force, used strong language, all to no purpose. At last our friend took that changing box, threw it in the air and let it drop, thud! He jumped upon it, kicked it, and, as far as he knows, it remains lie whitening upon that Manx hill yet. He is now a happy man; he owns no changing box, and never intends to.

Photographic journeying reminds me of the suggestion of Mr. Dunmore to send a list of suitable places with their capabilities and facilities succinctly and shortly stated. There can be no doubt such a list would be useful, and the suggestion will tend to rehabilitate the old recommendation—I forget whose—that the "Where-to-go-with-the-Camera" series of this JOURNAL should be reprinted in book form. I doubt whether it would pay; but if only the Editors would classify, condense, abstract, and otherwise reduce in bulk, and re-publish—after the style Mr. Dunmore suggests—this series, the thing would be started on a first-rate basis, and many ardent and skilful photographers who have either no time to contribute so fully as hitherto been done to the series or are deficient in confidence to

write a brief article, would feel no hesitation at adding his quota in Mr. Dunmore's style. Mr. Editors, will you not take the hint and start such a list forthwith? it would be invaluable, and ultimately might be reprinted with some probability of there being no loss through the transaction.

Technical printing is always a difficult matter to get done successfully and correctly, though I must congratulate the publishers of this periodical upon the successful way in which such printing is carried out in these pages. I wonder who is responsible for the benzole diagram on page 359. It is neatly set up, though it is rather wanting in symmetry. But I want to know what has become of the II atoms: it is a new kind of benzole that exists without hydrogen! The writer of the article experiences a difficulty in imagining how "pyrogallic" is made at the price, and is sure it cannot be made from gallic acid; but where is the need of isolating the acid from the galls? Processes have been published long ago for making "pyro" direct from the galls by sublimation. I remember making some in that manner nearly thirty years ago, and I am quite sure the process was quite as useful as Dr. Kenyon's method for preserving or storing solution of sulphate of iron. I think if he will keep his solution in a stoppered bottle, the stopper of which has been well greased with vaseline or other such compound, he will be able to keep his sulphate unchanged for a long period of time. His method is, no doubt, a successful one, but is too cumbersome; besides, he would find that the portion of solution in the tube in the neighbourhood of the pinchcock would be found oxidised after it had been left unused for a fortnight. At the very least, he should have recommended that some portion should be allowed to run to waste before taking a supply for mixing into a developer, if absolute freedom from oxidation be—as I should doubt—of such prime importance.

Still attracted by chemical matters, I would say, How is it that the hydrosulphurous acid method of development is introduced as a novelty by the French experimenters named in the account given in this JOURNAL for June 3? I have not my files of JOURNALS at hand to refer to, but I am sure that this method of developing was treated at length in an editorial given, I should say, at least a dozen years ago. "There is nothing new under the sun," apparently.

A writer over the signature of "Procella" goes out of his way to fall foul of metal slides for use in photo-micrography. Most cacophonous word that this is, I wish some one would invent a better! I cannot at all follow him in his complaint, for any one with much experience in such matters knows that where the objective without eye-piece is used, any loss of sharpness through the difference of a small fraction of an inch in the relative position of plate or focussing screen is absolutely unrecognisable when high powers are used.

I will conclude by giving my experience as to the keeping power of dry plates, with regard to which a recent correspondent wrote. I have some of a particular brand, which, to my thinking, are the best I ever employed, that are only about eighteen months old, yet are completely useless for about an inch and a half of margin round the whole of the plate; but, at the same time, I have other brands, purchased at a prior date, that appear to be as good now as on the day I first received them, the two sorts being stored in immediate juxtaposition.

FREE LANCE.

ACCESSORIES OF THE LANTERN.

CHAPTER IX.—THE MIXED GAS JET (*continued*).

HAVING decided upon the shape and aperture of the nipple (see last chapter), we have now to design the mixing chamber of the jet, for it must not be supposed that any method of conducting the gases to the nipple will suffice. There is no difficulty about the commingling of oxygen and coal gas; if they travel in company through a pipe three inches long and a quarter inch bore they will be as well mixed as is necessary to produce the best light. What we have to strive after is to supply the nipple with the two gases mixed together, and proceeding up the supply tube to the nipple in a condition of entire freedom from eddies and cross currents. If the gases reach the nipple with an eddy and a whirl there will be a loud roaring or hissing noise with a small aperture, and the light will go out altogether with a large one, owing to the flame "passing back."

When I mention small apertures, I refer to the size of bore

generally adopted for commercial jets, which is often not larger than one-twenty-fourth part of an inch in diameter; by a large aperture, I mean a bore of about one-thirtieth of an inch, which will consume three times as much gas as the former, and give three times as much light with the same gas pressure.

The chief advantage of the large apertures for screens of moderate size is the great reduction of the weights that have to be put on the pressure boards; a half-hundredweight will give as good a light with the large bore as three hundredweights with the small one, the two nipples being then about equal in the quantity of gas consumed.

If the mixed gas jet makes a noise while in action, and the nipple is not in fault, the noise can usually be stopped by inserting cotton wool in the pipe between the nipple and the mixing chamber in small quantity, so as not to sensibly lessen the amount of gas consumed. The action of the wool is simply to break up the miniature cross currents of the gases, and so produce the smooth flow necessary for a noiseless light. Such a cure is, of course, only a temporary one; it is far better to alter the metal work of the jet, or supply a new mixing chamber.

About a year ago I described in these pages the jet nozzle, shown in Fig. 1, which is a full size section. This pattern is the best I know of at present if great power of light is required; with an aperture of about one-twelfth of an inch, and a high gas pressure, a light of 800 candles can be had with it. It is made of brass in three

Fig. 1.

Fig. 2.

Fig. 3.

Sections of jets drawn full size.

parts. A is the nipple, a cone two inches long, and half an inch external diameter at the base, tapering to one-eighth of an inch at the point. The internal bore is also a cone, five-sixteenths of an inch diameter at the base, and one-fifteenth (or up to one-twelfth) at the orifice. B is the mixing chamber, shaped internally as an inverted cone, with a diameter of five-sixteenths of an inch at the top, and three-sixteenths of an inch at the bottom. At the lower end of B is inserted a brass plug, perforated with three or more parallel holes made as large as the size of the plug will admit. C is a small brass block, into which are screwed the pipes that convey the oxygen and coal gas respectively.

This nozzle is rather a long one, and might prove inconvenient in some lanterns; in such cases a nipple made like Fig. 2 may be used—this is a very effective and useful pattern, and will give a silent light of 600 candles. The upper piece D is nearly like A in Fig. 1; it screws on to E, in which is a brass plug one-fourth or five-sixteenths of an inch diameter, and one-fourth of an inch long. This plug is perforated with seven parallel holes, one being in the centre, and the other six arranged round it in a circle; these holes may be one-sixteenth of an inch in diameter. The piece E is screwed into a block similar to C, Fig. 1. If this pattern, Fig. 2, is still too long, the nozzle D may be shortened, but I do not recommend this

unless absolutely necessary, as a smaller aperture would have to be used.

These two jet nozzles are very different to the pattern generally adopted by opticians, and to change the latter style to those shown in Fig. 1 or Fig. 2 would probably be rather expensive, necessitating an entirely new front piece or mixing chamber. Those who would like to increase the power of their jets without interfering with the brasswork can do so by unscrewing the small nipple, with its platinum tip, and screwing in its place a brass nipple made like Fig. 3, which is twice as long as the ordinary nipple. Fig. 3 is made of a piece of brass wire, one-fourth of an inch in diameter, and about one and a half inches long. One end of it is tapped to fit the screw of the nozzle of the jet; the other end is made somewhat cone-shaped, so as to be one-eighth of an inch wide at the point. A hole, one-fourteenth of an inch in diameter, is then carefully drilled from end to end; this hole must have a smooth internal surface, and be of the same small diameter throughout. This nipple possesses in itself the property of destroying eddies in the gas, which, owing to the small size of the bore in comparison with its length, will have spent their force before reaching the orifice. It will therefore act well on any jet, and may even be screwed direct into a block like C, Fig. 1, though it is better to allow the gases to mix in a short curved tube before reaching the nipple, as is customary in commercial jets.

Fig. 3 is not quite so powerful as Figs. 1 and 2, but it will give a silent light of 400 candles, and with a higher pressure of gas a still better light, possibly accompanied by a little noise. The three patterns of jet nozzles here described are the outcome of a series of experiments I tried with the view of improving the power of the mixed gas jet, by which I was at first unable to get a better light than 200 candles—a most unsatisfactory illumination when screens of over twenty feet had to be used.

It must be distinctly understood that the various candle-powers stated above can only be obtained with coal gas. Pure hydrogen cannot be used with these large apertures, as the light instantly goes out through the flame passing back. Nor are these jets suitable for use with the ether tanks made to replace coal gas. The flame will burn, it is true, if there is a good pressure on the oxygen bag, and the light then is very brilliant. The three jets illustrated are perfectly silent when used with coal gas, yet with the ether tanks they make a powerful roaring noise, quite insupportable in a lecture exhibition. If a mixed gas jet is required to burn hydrogen or ether vapour, it must have a small aperture about one-twentieth of an inch diameter—a silent light of about 300 candles is then obtainable. Fortunately, few persons use anything but coal gas; ether tanks are unsafe unless Rev. Hardwick's ingenious pumice chambers are used to prevent explosions.

A powerful limelight will do more to increase the success of an exhibition on a large scale than superior quality in the slides can accomplish. I have noticed that a set of ordinary tinted photographs, worth, at the most, three shillings each, when shown by a light of 700 candles on an eighteen feet screen, produces a far better impression with an average audience than will the most elaborate and expensive slides, costing, perhaps, twenty shillings each, if the latter are shown with the ordinary commercial jets.

I have heard people who were not lanternists remark that the pictures in the first case were far superior in quality to the more expensive ones, although when the two sets of slides were shown by the same light the verdict was, of course, reversed.

ALBERT WM. SCOTT.

ON A MULTIPLEX DARK SLIDE FOR CARD-MOUNTED FILMS.

[A Communication to the Birmingham Photographic Society.]

At our last meeting I read a short paper on my *Card-mounted Flexible Glass Films*, and I should like to supplement it by a description of a slide which is much better suited for them than the ordinary single or double dark slide, as I consider that to have a perfect film is of little use unless you have also some contrivance which allows of the operator taking advantage of reduced weight of films to carry a greater number than he could plates.

I think the main object to be achieved by the use of films is to make a full day's work possible, if opportunity offers. I think nothing can

be more tantalising than to work with a limited number of plates or films.

The slide I wish to describe to you is a modification of what I have used for plates, but in consequence of the films being mounted on an opaque and light material, it is only half the trouble and half the work as compared with glass plates. I did not mention this in the paper at our last, as I had not proved the article in actual use, and romancing does not do instead of work and trial. I have had some years' practice at films in one shape or the other, and am free to say that before this last development of films I always preferred working with plates, not liking my own medicine. With the trials I have made the last month, I conclude I shall not go back to plates for any outdoor purpose.

The slide, as you see, is about the thickness of two double dark slides. It will hold thirty card-mounted films; these are placed in the slide with the sensitive sides all facing the front, and do not require anything between the sensitive surface of one film and the back of the next film. When an exposure has been made, all that is needed is to remove the exposed film from the front of the slide to the back. This is such a simple process that it can be done by feeling in the dark bag. As soon as the exposed film is removed, the one underneath is ready for exposure.

The proper order to proceed is to pass the slide into the dark bag with the sensitive side of the films uppermost, to unbolt the slide, take the exposed film from the top of the box, lay it in the bag, fasten the bolt, turn the slide over, and insert the exposed film, and repeating this until a distinctive feeling card has come to the surface, which will show that all have been exposed. It is easy to change a film the whole-plate size in thirty seconds. My son says he can change the $\frac{1}{2}$ size in ten seconds. Last Saturday, at Kenilworth, I made twenty-six exposures in rather less than two hours. There are here a number of negatives and prints taken from the films for your inspection, which are taken in the slide I am describing. I will give the weight of several sizes of slides fully charged with thirty films:— $\frac{1}{4}$ size, 17 ounces; $\frac{1}{2}$ size, 28 ounces; $\frac{3}{4}$ size, 44 ounces. The slide can be adapted to any camera.

CONTINENTAL PHOTOGRAPHY.

[Translations and Abridgments.]

INTENSIFYING NEGATIVES.

M. RICHARD, of Dampierre, writes to the Photographic Society of France that a negative is reduced by being plunged into a solution of red prussiate of potash, and is equally reduced by a solution of perchloride of iron, but that if it be first plunged into perchloride of iron, then into red prussiate of potash, it assumes a bluish green colour all over, and becomes vigorous almost beyond limit, according to the strength of the solutions and the number of times it is transferred from the one to the other. If the two baths be mixed the effect takes place at once, and further immersions have no additional effect. It is necessary to well wash the surface of the negative between the immersions in each of the two baths. The green tint passes easily to bright blue by a little washing with a feeble solution of ammonia. It remains to be ascertained whether the colours unfavourable to printing can be discharged by any method without at the same time weakening the negative; possibly in some cases the blue tint may prove to be of advantage.—*Bulletin de la Société Française de Photographie.*

THE DEATH OF M. LEMERCIER.

Le Moniteur de la Photographie announces with regret the death of M. Lemerrier, whose name has long been connected with photography. He purchased the patents of Poitevin and of Albert, of Munich, and in his workshops the first important works by photo-mechanical processes in France were printed.

AN ANILINE BLACK PRINTING PROCESS.

Herr Endemann writes that the paper intended for use in this process should be well sized with an aqueous solution of gelatine in the proportion of one to fifty. The sensitising solution consists of:—

Chloride of sodium	48 grammes.
Bichromate of potash	48 "
Vanadate of soda	0 gr. 10.
Distilled water	960 c.c.

Another solution is made of:—

Sulphuric acid	96 c.c.
Water	480 "

When this is cold it is added to the first solution; the paper is floated upon the mixture, and then allowed to dry in a dark place.

The paper when dry, or while slightly damp, is then exposed under a printing frame for about seven minutes to the action of light, after which it is kept in the dark until it is desired to develop the image. It is then exposed for one minute to a mixture of the vapours of water and aniline, next it is placed in an atmosphere of vapour of water kept at a temperature of from 24° C. to 30° C. The image is thus developed in black lines upon a green ground. To remove the green colour it suffices to soak the paper in a one to six solution of ammonia; the print has then to be dried and pressed.—*Photographisches Archiv.*

INCREASING THE SENSITIVENESS OF COLLODIO-BROMIDE PLATES.

A plate is coated with washed collodio-bromide emulsion, in which the haloid salts are bromide of zinc and chloride of cadmium in the proportion of four to one. After coating with the emulsion, the plate is washed in water, then flooded with the following solution:—

Beer	500 c.c.
Water	500 "
Egg albumen	25 "
Ammonia.....	30 "

The plate is again washed, and then dipped in the following solution:—

Pyrogallol	1 gramme.
Beer	500 c.c.

The plate, when dry, is much more sensitive than one prepared by the ordinary wet collodion process.—*Photographisches Archiv.*

NEW EXPERIMENTS ON THE BITUMEN PROCESS.

The bitumen process is well known, but Professor Husnik has published some new details about it. He says that pulverised Syrian asphalt should be dissolved in double its weight of German essence of turpentine, and agitated every half hour for two days, until a thick syrup is obtained. French or Austrian essences do not give the same results. By experiment the operator finds out what quantity of sulphuric ether should be employed to dissolve the useful portion of the asphalt. To do this the syrupy liquor is mixed with some of the ether, shaken up with it, and then allowed to rest in a covered vessel; the supernatant solution is then poured off, and more ether shaken up with the sediment and similarly poured off, until additional ether will dissolve scarcely any more. This point can be ascertained by allowing a little of the later ethereal solutions to evaporate. These ethereal solutions should be mixed together, the ether nearly all distilled off, and the thick residue spread out upon zinc plates until it is almost completely dry; the drying will occupy three days, or perhaps four. All these manipulations should be performed by daylight, and not near a candle flame or fire.

The purified asphalt should then be dissolved in chloroform, or in benzine which has been completely freed from water, otherwise the solution will not cover the plate evenly. In three or four minutes this solution will give a dry film of asphalt. With the benzine mix one per cent. of Venice turpentine, add the asphalt, and shake until it is dissolved. It is then diluted to such an extent that a film of it dried upon zinc has a golden yellow colour. The bottle to hold the solution should be made slightly warm, after having been washed with water and well dried by first washing with alcohol and afterwards with ether. Its mouth is closed with a cork.

To use the solution, a well polished plate of zinc or copper is coated with it by the aid of a brush, and the plate is then placed upon a truly horizontal whirling-table, in such a way that by rotation a perfectly even film is obtained.

The time of exposure under the negative is from five to thirteen minutes for sunlight, and from three-quarters of an hour to four hours for printing in the shade. Unfortunately the zinc plate must be very thick for etching purposes, and very vigorous negatives are necessary. The most important point is the development of the image, which must be done in a flat dish and by simple washing, for the application of a brush would injure the image. The parts acted upon by light should appear in three or four minutes. The turpentine is then poured off, and the plate washed under a current of water. The plate is next placed in an acid bath, strength one to twenty, drained, dried, varnished, inked, then retouched and engraved in the ordinary way.—*L'Amateur Photographe.*

Class I.: *Oil Paintings.*—Paintings on canvas, on panel, and on other grounds.

Class II.: *Various Paintings, Drawings, &c.*—Miniatures, water-colour paintings, pastels, and drawings of every kind; paintings on enamel, earthenware, and porcelain; designs in glass and clay; cartoons for stained glass windows and frescoes, &c.

Packages forwarded from countries and colonies represented at the Exhibition should be addressed, "To the Commissioner for —, Centennial International Exhibition, 1888, Melbourne, Victoria, Australia," and the following information must be written on the outside of each package:— (1), The country from which the package comes. (2), Name or firm of exhibitor. (3), Address of the exhibitor. (4), Group and class to which exhibits belong. (5), Total number of packages sent by same exhibitor. (6), Serial number of that particular package. Each package must contain a list of contents. Packages containing goods intended for the Exhibition must likewise have painted on them, as a distinctive mark, the following letters and figures within a triangle, thus—"C. I. E. M. 1888." Packages from foreign countries must also be marked with the colours and devices of their national flag. Foreign Commissioners are particularly requested to send to the Executive Commissioners, Melbourne, as soon as possible, a specification of the packages forwarded, with their distinguishing marks.

Exhibits will be admitted free of duty for the purpose of exhibition. Customs entries, transportation, receiving, unpacking, and arranging the products for exhibition must be undertaken by the exhibitor at his own expense. No charge will be made for carriage of goods intended for exhibition over the railway lines. Arrangements will be made by which all goods intended for exhibition can be carted from the wharves, or the several railway stations, to the Exhibition grounds at a fixed scale of charges.

ADVANTAGES OF ENLARGING FROM SMALL NEGATIVES.

At a meeting of the Camera Club of Syracuse, N.Y., held on March 18, 1887, a paper was read by Dr. F. W. Marlow on some of the advantages for the landscape photographer of using a small camera with short-focus lens, and enlarging from the negative thus obtained. It was pointed out that there is only one point from which a photograph can be correctly seen, that point being situated at the focal distance of the lens in front of the centre of the picture. Under this condition only do objects in the picture occupy the same angle with regard to the eye that they do in nature.

The results of looking at photographs from any other than the correct point of view, such as the dwarfing of distant hills, and the magnifying of objects in the foreground, such as hands and feet, were then referred to. It was stated that photographs are very seldom done the justice of being looked at from the proper point of view, in proof of which it was instanced that few amateur photographers could tell the exact focal length of their own lenses, and that photographs of landscapes, buildings, &c., were almost invariably sold without any note as to the focal length of the lens with which they were taken. Photographs should have a note on the mount, indicating the proper point of view.

People with ordinary sight find it inconvenient or wearisome to look at photographs at a shorter distance than twelve inches, a greater distance even being generally preferred. (The use of a convex lens or the existence of near-sightedness permits a photograph to be brought to any required distance.)

For this reason a direct photograph ought not to be made with a lens of less than twelve inches focus, considerably longer focus even being preferable.

A long-focus lens involves a large and heavy camera, large plates, &c. (unless the photographer be satisfied with including a very narrow angle in his picture), making the outfit too heavy and cumbersome to be carried far.

Short-focus lenses, then, produce pictures which cannot be looked at with ease from the proper point of view; long-focus lenses involve too cumbersome an apparatus. The way out of the difficulty is to use a small camera and short-focus lens for making the negative, and to enlarge so that the picture may be put at a convenient distance from the eye and still occupy the same angle that it does in nature.

Besides the obvious advantages of lightness, small space, inexpensive-ness, &c.; there are two other greater but less obvious advantages:—First, much greater definition can be obtained in the near foreground by this method than by taking the photograph direct with a long-focus lens. For instance, with a lens of twenty inches focal length, the distance being in focus, the nearest point which can be said to have sharp definition on the focussing plate is 25.5 metres in front of the lens. With a lens of four inches focal length, everything up to a distance of 1.1 metres is sharply defined. This definition can be reproduced in the enlargement. This is an enormous difference in favour of enlargements from negatives taken with short-focus lenses. The second advantage which, so far as is known to the writer, has not been previously described, is that a single landscape lens can be used for all subjects, even those containing straight lines, both for the negative and for the enlargement, the distortion produced in the negative being corrected in the enlargement.

On the general principle that a ray of light in passing between two

CENTENNIAL INTERNATIONAL EXHIBITION, MELBOURNE, AUSTRALIA.

THERE is to be a great Exhibition in Melbourne next year. Photographs do not rank as *Works of Art*, but are relegated to the second group under *Education and Instruction: Apparatus and Processes of the Liberal Arts*, as follows:—

points *a* and *b* lies in the same path whether its direction be from *a* to *b* or from *b* to *a*, whatever refracting media it passes through, it seems fair to suppose that if the direction of the rays of light in the camera were reversed, and the negative be made the source of light, that rays of light coming from the curved lines, &c., would after emergence from the lens reassume their original paths, and no distortion would be observable in the image so formed. There would be an exact reproduction of nature.

To investigate matters a little more closely; the distortion which accompanies the use of the single landscape lens is due to the use of the diaphragm, the kind and degree of the distortion varying with the relation of the diaphragm to, and its distance from, the lens. When the diaphragm is in front of the lens, the distortion produced is "barrel-shaped," straight lines becoming curved, with their convexity outwards. When the diaphragm is behind the lens, the convexity of the curve is inwards.

The further away from the lens the diaphragm is placed, the greater is the distortion. The method ordinarily employed to correct this distortion is to place a lens both in front of and behind the diaphragm.

The same correction is virtually made by using a diaphragm in front of the lens when making the negative, and behind it when making the enlargement. In the first process there is a tendency to the curvature of straight lines inwards, and in the second to the curvature of straight lines outwards; the one counteracts the other and leaves the lines finally straight.

This is probably only absolutely true when the subject is enlarged to its natural size; in smaller enlargements, some of the same kind of curvature seen in the negative may be expected to remain in the enlargement, but even this may be got rid of by increasing the distance between the diaphragm and the lens during the enlarging process.

Direct photographs and enlargements were shown, demonstrating the correction of distortion to the satisfaction of all members present.

THE ANNUAL VISITATION OF THE ROYAL OBSERVATORY.

From the Report of the Astronomer-Royal to the Board of Visitors, read at the annual visitation of the Royal Observatory, we learn that above the extended portion of the upper computing room a dome 18 feet in diameter is to be erected, in which it is proposed to mount a Cooke 6-inch equatorial, a photo-heliograph tube being attached to the same mounting. The combined instrument will command a complete view of the sun throughout the day—an important consideration, as the work of the present photo-heliograph is seriously interfered with by trees and the Lassell dome. The new instrument will be available for occultations, phenomena of Jupiter's satellites, and other occasional observations.

Various additions have been made to the Lassell equatorial with a view to making it available for astronomical photography and for general use. A delicate slow motion in R.A. (with differential wheels) and a firm N.P.D. clamping arm with fine motion in N.P.D. have been applied, the steadiness and general usefulness of the telescope being greatly increased by these additions. The Corbett 6½-inch refractor has been mounted below the tube of the reflector and parallel to it to serve as a directing telescope in taking photographs, and also for observation of occasional phenomena. A camera to take circular plates 8½ inches in diameter (giving a field 1° 58' in diameter) has been mounted at the principal focus of the Lassell mirror, and some trial photographs of the moon, Procyon, Regulus, γ Leonis, and Præsepe, have been taken.

The construction of the new 28-inch refractor has been delayed by difficulty in obtaining the discs of glass. Messrs. Chance are engaged in removing a bunch of fine veins from the flint glass disc, and have every hope of being able very shortly to report the disc practically perfect; and M. Feil's successor has successfully moulded a crown disc from which he believes that he has removed all defects.

The south-east and Sheepshanks equatorials are in good order. Some trouble has been experienced with the water supply for the driving clock of the former instrument, and an alteration in the arrangements for maintaining the pressure has been made at the Kent Waterworks, since which the working has been found quite satisfactory.

The Cooke 6-inch equatorial is being mounted in the south ground for trial as to the practicability of using curved plates for stellar photography and other questions which have been raised at the Paris Conference on Astronomical Photography.

A photographic corrector, consisting of a concave crown and convex flint lens (in contact), placed about 30 inches within the focus, has been applied to the telescope of the south-east equatorial to correct the chromatic aberration of the object glass for the photographic rays without alteration of the focal length. A Dallmeyer doublet (formerly used in the photo-heliograph) has been employed to enlarge the primary image about 7½ times, so as to give on the photographic plate an image on a scale of about 0.45 inch to one minute of arc, or 15 inches to the sun's diameter. A number of trial photographs of Castor, γ Virginis, Venus, Jupiter, and Saturn, have been obtained. The photographs of the double stars appear to be susceptible of very accurate measurement, and several of the photographs of Jupiter show the four satellites, the belts, and the red spot. A photograph of γ Virginis, showing the components widely separated, has also been taken at the primary focus, the Dallmeyer enlarging doublet having been removed. It is intended also

to use the photographic corrector with the Dallmeyer doublet to obtain photographs on a large scale of sunspots, craters on the moon, and other objects of small angular dimensions. The field of view with the photographic corrector is necessarily very restricted.

For the year 1886, Greenwich photographs are available on 199 days, and photographs from India and Mauritius filling up the gaps in the series on 161 days, making a total of 363 days out of the 365 on which photographs have been measured, the record being thus practically complete for 1886.

As regards the photographic reductions:—The Greenwich photographs have been measured in duplicate as far as 1887, April 28, and the measures have been completely reduced so as to exhibit heliographic longitudes and latitudes of spots and areas of spots and faculae. The photographs from India and Mauritius have been received from the Solar Physics Committee as far as March 10 and February 20 respectively, and these have all been measured, and the measures completely reduced.

The Report concludes with the following general remarks:—"As the result of an International Congress on Astronomical Photography held at Paris in April on the invitation of the French Academy of Sciences, at which fifty-six representative astronomers from all parts of the world were present, a scheme has been approved for the formation of a photographic map of the heavens by the concerted action of a number of observatories in both hemispheres. This scheme provides for two series of photographs, the one intended to contain all stars down to the fourteenth magnitude inclusive, and the other, taken with short exposure, specially designed to give accurate positions of brighter stars down to the eleventh magnitude, so that it may be possible to form an extensive catalogue of reference stars for the first series, and thus to give the means of accurately determining the position of any star on the photographic map down to the fourteenth magnitude. The instruments with which this work is to be jointly carried out are to be photographic refractors of 0.33m. (13 inches) aperture and 3.43m. (11 feet 3 inches) focal length, and the directors of ten observatories have already announced that they are prepared to take part in the enterprise."

IMPROVEMENTS IN THE MANNER OF APPLYING GELATINE AS A SUBSTITUTE FOR PAPER OR GLASS IN THE MANUFACTURE OF DRY PLATES FOR PHOTOGRAPHIC PURPOSES.

No. 9460. JOSEPH BROWN, 3, Stanley-terrace, Norbiton, Kingston-on-Thames, Surrey.—*July 21, 1886.*

This invention has for its object improvements in the use of transparent gelatine as a substitute for glass or paper for the support of the sensitive gelatinous films used for photographic purposes.

My mode of proceeding is as follows: I take a sheet of paper, which I coat with a layer of gelatine. This, when dry, I coat with another layer of wax or grease. On this surface I proceed to place a sheet of insensitive transparent gelatine by means of a vacuum. This sheet of gelatine it has sufficiently dried on its support I proceed to coat with a layer of any of the usual sensitive photographic emulsions. This is left to dry, and then cut up to any required size. This prepared gelatine attached to its paper support is now ready to receive the photographic image. I now proceed to develop the image by any of the well-known methods. After the image is developed, I proceed to place the photographic image face downwards on a sheet of glass or other prepared surface; when sufficiently dry, I take away the paper support and leave the coated gelatine to dry completely; when dry, I lift up the sheet of gelatine which carries with it the photographic image, and which is now ready to be printed from by any of the usual methods.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The process herein mentioned of applying gelatine as a substitute for glass or paper in the manufacture of dry plates for photographic purposes in the manner and by the means and for the purposes herein set forth.

AN IMPROVED PHOTOGRAPHIC CAMERA STAND.

No. 3270. JAMES LAUDER, 43, Blessington-street, Dublin.—*March 3, 1887.*

The object of this invention is to enable the photographer to take photographs of any object even as low as the ground, whilst, by an instantaneous movement, an object can be taken at a great height.

The simplicity of construction of the stand together with its facility and rapidity of manipulation render it of considerable importance, being far superior to any contrivance at present adopted, as much time and labour is required to wind up the machines at present in vogue.

The camera stand, the subject of the present invention, consists of a vertical framework composed of four uprights or standards of gun-barrel or some suitable tubing, held together by frames of the same material top and bottom, each of the standards is provided at the lower extremity with a caster or roller on which the stand runs.

The table or board on which the camera rests is a suspended one, being hung from its corners by weighted cords or chains, the weights running up and down inside the hollow uprights of the frame, whilst the cords or chains pass over sheaves or pulleys mounted at the angles of junction of the framing of the stand, or they may be placed in any convenient position, and if desirable a less number both of cords, chains and pulleys may be used.

The movable and slidingly adjustable table or board consists of an upper frame of wood or other suitable substance, to which the camera is attached, in conjunction with a second frame situated or placed beneath the first or upper one, and sliding in grooves arranged for the purpose on the upper frame.

The outer angles of each frame are curved to suit the shape of the four uprights, between, and up and down which this suspended table travels.

Each of the curved corners are padded with indiarubber to ensure contact, and give it a hold on the uprights when in position.

The two frames are kept distended and in contact with the four supports by aid of indiarubber or other springs. The object of this arrangement is to retain the table rigidly in any position in which it may be placed.

The table is released from its rigid position by gripping in the hand and drawing together two handles, one mounted on each frame, or by some arrangement producing a like result; this movement counteracts the effects of the springs, and the table being reduced in size by this means admits of its being raised or lowered to any angle or position that may be required.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. James Glaisher, F.R.S., President, occupied the chair.

Sir Coutts Lindsay, Bart., Mr. Octavius Smith, and the Hon. Reginald Dudley Brougham, were elected members of the Society.

Mr. EDGAR W. CROOKSHANK read a paper upon *Photo-Micrography and its Value in Biological Research*, in which he set forth the results of two years' work on minute organisms. He described various forms of apparatus previously used in such work, and said that photographs of small organisms were of more value than drawings, because they were free from any unconscious bias on the part of the observer, whose drawings might satisfy himself, but did not always give satisfaction to the sceptical. This was the reason why Koch availed himself of photography, and in 1877 published a series of photographs of dried and stained bacteria; the *flagella* of *Spirilla* were photographed by him after the object had been stained brown; those objects which admitted only of being stained blue or red were photographed upon eosined collodion, but the exposures were long and the results indistinct. In 1881 Koch published a new series of photographs, some of which were excellent, especially those in which the object had been stained brown. In 1885 Hauser, of Erlanger, produced photographs of bacteria, showing an advance on all that had been done before; they were of practical value. His specimens had been stained brown and mounted with Canada balsam, a method which cannot be applied in all cases. Dr. Van Ermengen showed a way out of previous difficulties; he first proved the distinct value of orthochromatic plates in such work by producing photographs of *Comma Bacilli* which had been stained red. In 1881 Clayton & Tailor issued orthochromatic plates commercially in Paris; he (Mr. Crookshank) used their plates in photo-micrographic work, and employed apparatus made for him by Messrs. Swift & Son. The apparatus consisted of a oxyhydrogen lantern, with a three-inch condenser, consisting of two plano-convex lenses; the light next passed through an Abbe condenser, which concentrated it upon the object, which was held upon the wide stage of a Zeiss's stand; the said stand was firmly held to the baseboard by clamps. The parts of the apparatus just described, including the microscope, could be turned round at right angles and away from the camera, so that the observer could properly centre the light and the parts of the apparatus, and get any desired part of the object into the field of view with comfort; this done the arrangement was turned back, and the camera pushed up to it, so that a tube in front of it made a light-tight joint with the eyepiece of the microscope. The whole apparatus could be turned up on its stand and used in a vertical position, or to reduce vibration to a minimum it could be taken off its stand and clamped to the wall of the room. The camera was of such length that when focussing he could reach the fine adjustment screw of the microscope with his hand. He often worked with the homogeneous immersion powers of Zeiss and of Powell & Leland. Abbe's condenser was good for optical purposes, but, because it was fixed, he usually substituted another for it in photographic work. He found that in working with the exceptionally high powers used in photographing bacteria, that his exposures with the oxyhydrogen light were usually

two or three seconds, but with a paraffine light from two minutes to half an hour; he was well satisfied with the action of the oxyhydrogen limelight. The exposures were made by means of a shutter inside the camera. When using the one-twenty-fifth oil immersion objective, a low power was screwed to the microscope first, and a bright little spot of light formed on the line by a small flame; the apparatus was then so adjusted that the small spot of light was accurately centred; the high power was then put in; some little time was then consumed in selecting the best part of the object to photograph, and much time was spent in focussing properly upon the ground-glass. He here exhibited a photograph of *anthrax*, the cause of the wool-sorters' disease, magnified 700 diameters, and an enlargement thereof upon Eastman's paper 4000 times the diameter of the object. As an illustration of the practical value of photo-micrography, he said that Dr. Lewis, of India, had photographed some organisms in the blood of bats, and the prints had chiefly enabled the organisms to be identified with some found in the common brown rat of this country. Photo-micrographs had also settled scientific disputes. Koch discovered that consumption is due to a little organism which has a beaded appearance like a rosary chain, and Koch stated that the little bright spots between the beads were the spores of this organism. He (Mr. Crookshank) had long hesitated to accept that view; he thought that they were dealing with a delicate rod with protoplasmic contents which had coagulated in the mounting, and so produced beads; he denied that the intervals between the little beads were spores; he exhibited a photograph of the organism of 700 diameters, also a print enlarged to 7000 diameters, and said that had any spores been present, those photographs would have made the fact obvious. He then exhibited a photograph of the *flagellum* of *Spirillum*; the object had been stained with gentian dye.

Dr. LINDSAY JOHNSON found that his own condensers gave two cones of light of different foci, and that that interfered with good photographic work. How did Mr. Crookshank avoid that?

Mr. CROOKSHANK used Swift's lantern condensers, and took care that the light from them filled the aperture of the Abbe's or other condenser of the microscope.

Mr. W. E. DEBENHAM said that a camera with swing back, with the back placed very much upon the swing while taking a photograph, gave a ready means of telling the difference between the chemical and visual focus of any objective.

Mr. J. A. HARRISON stated that with a plate placed at an angle in the pantascopic camera, and a series of images at fixed distances taken thereon through the slit, the difference between the chemical and visual foci of an objective was readily determined.

Mr. CROOKSHANK thought that there was no plan so good as having the objective perfect, especially as they had to pay a long price for it, and to avoid mechanical corrections, especially in using the high powers of which he had spoken, to which the ordinary powers used in photo-micrography presented mere child's play in photographic work.

The PRESIDENT remarked that the photographing of bacteria was an achievement with which they were all pleased. He added that the last day for the receipt of pictures for the Exhibition was September 21, and that the *soirée* would be held on October 1. The judges were Messrs. W. Cobb, England, Donkin, Hollyer, Mendelssohn, and Davison. The jury for apparatus consisted of Messrs. Bolas, Addenbrooke, Cadlett, and Trueman Wood.

Dr. DONKIN remarked that he had taken the liberty of inviting Herr P. Schlossman to exhibit numerous prints of the instantaneous photographs of animals taken by Ottomar Anschütz, of Lissa, who had received grants in aid of his work from the Prussian government.

A great number of the photographs were then exhibited, and included those of the flying stork, to which our special correspondent in Belgium invited attention last autumn.

The proceedings then closed.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday night, June 9, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. L. Medland presided.

The Chairman exhibited five negatives taken at Loughton.

The HON. SECRETARY stated that he had received a letter from Mr. Dunmore, of the Photographic Club, asking if the members of the Association would join it and other photographic societies in a photographic excursion to Watford on Jubilee Day, June 21.

The HON. SECRETARY announced that the Lord Provost of Glasgow would open the Photographic Convention to be held in that city early in July.

Mr. W. H. HARRISON asked whether all varieties of dextrine had the hygroscopic nature stated at the last meeting by Mr. Cowan. Dextrine was made in many different ways, and Mr. Charles Blackburn, of Didsbury, had exerted himself to get several commercial samples sent to him from manufacturers; most of the samples were of a light brownish yellow colour, and contained traces of acid which calico printers prefer to be present. The makers had sent him, also, a special specimen, labelled, "Low temperature dextrine," quite white and free from acid. No commercial samples of dextrine were chemically pure; pure dextrine, with all foreign matters separated by alcoholic treatment, being expensive and difficult to make, and, as yet, of no special use.

Mr. A. COWAN responded that, so far as his experience went, all varieties of dextrine were more or less hygroscopic. The yellower varieties had the stronger adhesive properties.

Mr. E. CLIFTON said that the old red postage stamps were backed with dextrine.

Mr. A. L. HENDERSON remarked that postage stamps are now backed with a mixture of gelatine and dextrine. The dextrine is put in to promote quicker drying.

Mr. T. BERRY stated that about fifteen years ago a firm with which he was connected mounted all their prints with dextrine, and the prints are now in as good condition as ever; yellow dextrine was used, dissolved in cold water. It was an advantage to be able to use a cold solution.

Mr. F. W. COX asked if gum tragacanth could be used for mounting prints. Mr. HENDERSON replied that it was difficult stuff to lay on. A prize of fifty guineas was once offered by some society for a good mountant, and the man who won it had recommended a mixture of gum tragacanth and gum arabic; the latter made the former more easy to use.

Mr. W. M. ASHMAN said that mouth-glue was a mixture of dextrine, gelatine and sugar, and when dissolved in water did well for mounting prints.

Mr. CLIFTON said that the London Paste Company were issuing some excellent stuff, quite common in America, and used largely by printers; it will keep any length of time, and can be diluted as desired. It is alleged to contain nothing which will injure photographs.

Mr. W. H. PRESTWICH asked the best way to mount prints in a book without producing cockling.

Mr. COWAN did not know how to do it without mounting the prints first, and making the leaves into a book afterwards.

Mr. CLIFTON said that very thick gum should be poured on to the back of the print, then distributed with the back of a knife, and the print then quickly pressed down upon the page before the paper had time to expand.

Mr. COX wished to know how to restore an Eastman's print which had yellowed.

Mr. A. PRINGLE thought that it would be difficult. Eastman's paper had a distinct cream colour of its own. He found that it was necessary to leave the prints long in the fixing bath; he never left them in it less than twenty minutes, and often left them in it for an hour.

Mr. J. B. B. WELLINGTON asked what would give a brown and aged look to prints.

Mr. CLIFTON replied that there was nothing better than coffee.

Mr. BERRY said that permanganate of potash was good.

Mr. PRINGLE had seen a platinum print of beautiful tone produced lately by Mr. H. P. Robinson.

Mr. CLIFTON stated that there is a regular trade known as "worm-eaters;" the men eat holes in wood with a fine drill, to give it an antique look; the earlier plan was to fire small shot into it.

The CHAIRMAN called attention to a description of an American camera which would take twenty-four plates without dark slides, and bring them up for exposure automatically when required; it only cost, lens and all, £3 15s. for the $3\frac{1}{2} \times 4\frac{1}{2}$ size.

Mr. CLIFTON remarked that practically it was Starnes's camera, but with a kind of revolving stereoscopic slide arrangement added.

Mr. PRESTWICH said that the meeting would be glad to hear that a member of that Association, Mr. Jarman, had just invented and put to work an excellent machine for driving tramscars by electricity.

The meeting then broke up.

CAMERA CLUB.

At a meeting on Thursday, June 9, Mr. W. H. Hyslop in the chair, an exhibition was given by Mr. T. M. Brownrigg of a set of lantern slides made from negatives taken during a recent tour in Switzerland and Italy.

Previous to the slides being shown the HON. SECRETARY drew attention to some pictures (to be seen on the Club walls) lent by Mr. Bolas, one a collotype print in a great variety of colours, and the others photographs by Mr. F. C. Beach of the "Celtic," showing the effects upon that vessel of her recent collision with the "Britannic."

Mr. Brownrigg's transparencies included some fine photographs of interiors and statuary taken under difficulties in the galleries at Rome and Florence, also pictures taken at Capri, Alpine scenery, and a humorous set in caricature of scenes from *Romeo and Juliet*. The gem of the collection was a picture representing sunset over a broad expanse of water.

The proceedings terminated with a vote of thanks to Mr. Brownrigg.

On Thursday, June 23, at nine o'clock, another exhibition of lantern slides will be given. Slides will be contributed by Messrs. J. Gale, J. B. B. Wellington, T. M. Brownrigg, C. B. Wright, and other members and friends.

The next Club excursion, to Marlow and neighbouring points upon the river, is fixed for Saturday, June 25.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Committee of this Association held a meeting on the 9th instant.

The minutes of the previous meeting having been read and confirmed, Messrs. H. Kuntzen, C. I. Cowie, F. J. Goode, W. Ingle, R. W. Goodlen, T. Charters White, W. H. Walker, J. Jackson, H. E. Davis, J. Martin, G. Aspinall, E. Hooker, A. J. Wallace, J. G. Bryan, C. J. Parker, W. Ward, J. R. Jones, J. H. German, and A. Gandy, were elected members of the Association.

An application for assistance was then dealt with, and the sum of £6 granted the applicant.

The SECRETARY reported that Mr. J. Chester Jervis, winner of the £3 3s. prize, and Mr. Alfred Green, winner of the £1 1s. prize, given by the *Amateur Photographer*, had made donations to the Association of those amounts. Messrs. Perken, Son, & Rayment, and "S. B." had also contributed £1 1s. each to the funds.

Employers willing to assist the Committee in their work are desired to write to the Secretary for a supply of handbills for distribution amongst their employees.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held at Myddelton Hall, Islington, N., on Tuesday, June 7, Mr. J. Traill Taylor, President, in the chair, Messrs. J. T. Blonfield, H. Coppin, A. P. Higgins, J. Jackson, and W. H. Walker, were elected members of the Society.

A large number of views and groups taken at the excursions to Chiddingstone and Epping Forest were exhibited.

The PRESIDENT showed and explained the working of an American detective camera made by the Scovill Manufacturing Company of New York, having a very quick-acting lens made expressly for it by Wray, of London. This

camera was passed round among the members; its various actions were examined with much interest and gave rise to many inquiries. He also exhibited the Grimston shutter and another.

Mr. L. Medland showed a shutter which could be regulated to give exposures from one-fiftieth of a second.

In a short discussion upon the development of gelatino-bromide papers, it was stated that the secret of producing velvety black shadows in the pictures lay in the use of old ferrous oxalate developer. After use the developer should be placed in a bottle and exposed to sunlight, a little citric acid being added before again using.

Mr. A. MACKIE said that he had been frequently congratulated recently by non-photographic friends on the success now achieved of photography in natural colours. He had had to explain that we are, in that direction, very little in advance of the photographers of thirty years ago. The President would perhaps tell them something about the colouring processes of which they have heard so much lately.

Mr. TAYLOR then gave a detailed account of the Cellerier process of colouring photographs, so far as could be ascertained by him from an inspection of such as had been submitted to him for that purpose. It was, he said, merely a process of applying colours at the back of a transparent print, such as most of them had long been acquainted with.

In consequence of the third Tuesday of this month being the Jubilee day, the next meeting will be held on Friday, the 17th instant, when Mr. E. Dunmore will deliver a lecture on *Photography Past and Present*. Visitors are invited.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of this Society was held at the Greyhound Hotel, Dulwich, on Wednesday, June 8.—Mr. F. E. Harding in the chair.

After the usual business, Mr. C. ESKELL read a paper on *Collotype Printing*. He described the use of the principal apparatus necessary, and explained his method of making collotypic prints. Mr. ESKELL gave simple formulae for substratum and sensitive coatings for the ground-glass plate, and stated that there need be no difficulty in any amateur working the process at a moderate cost; the whole of his outfit was obtained at a cost of about £3. Some very good examples of collotype printing executed by Mr. ESKELL were passed round.

At the next meeting of this Society, on Wednesday, June 22, at eight o'clock, members are invited to bring their photographic outfits ready for field work, for the purpose of comparing the merits and demerits of the various parts of their apparatus. Matters relating to field work generally will also be discussed.

Non-members are also invited to attend this meeting, bringing their apparatus with them.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

THE first excursion for the present session took place on the 9th instant, when sixteen members and friends proceeded by train to Coventry. Here the party were met by a break, and after a most enjoyable drive through beautiful country along one of the most famed, picturesque lanes in the country, the party arrived at Stoneleigh Abbey, the seat of Lord Leigh, an ancient and historical building. The party subsequently adjourned to the "Queen and Castle" Hotel, where lunch was provided. They then proceeded to Warwick Castle, where they were reinforced by several additions to their party. After about two hours spent in and about the Castle and grounds the apparatus were packed and the party drove to Kenilworth Station, where they embarked for home. In the aggregate sixty-seven plates were exposed, ranging in size from quarter-plate to 12×10 , resulting in an excellent average of successful pictures.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of the above was held in the Free Public Library on Thursday evening, the 9th instant.—The President, Mr. J. A. Forrest, in the chair.

Mr. A. Penberton was elected a member of the Association.

A circular was read from the Secretary of the Royal Meteorological Society, London, relative to photographing lightning flashes. None of the members had ever attempted this sort of work, but, the matter exciting some interest, it was felt that it should be tried the first opportunity. The photography of lightning does not present any particular difficulties. If a rapid plate and an ordinary rapid doublet with full aperture be left uncovered at night during a thunderstorm for a short time, flashes of lightning will, after development, be found in some cases to have impressed themselves upon the plate. The only difficulty is the uncertainty whether any particular flash will happen to have been in the field of view; this, however, can easily be obviated by using a suitable meter.

A number of specimens of ceramic photography from the potteries of Messrs. Sampson Bridgwood & Son, Longton, Staffordshire, were exhibited by the Secretary, and much admired, especially so several which had been hand coloured. The firm print from members' own negatives, and their price is not excessive, considering the difficulty and indestructibility of the work.

After some conversation on the approaching Conference and the desirability of having a representative from the Association there, it was, on the resolution of Mr. P. LANGRISH, seconded by Mr. H. LUTON, and agreed to, that the President be the one selected for the honour, the Association disbursing a part of his expenses.

A number of lenses of various sizes and price from the establishment of Messrs. Newton, Liverpool, were exhibited by Mr. W. P. Riley.

Mr. F. N. EATON had an exhibit, interesting to those photographers who study ways and means, of a number of developing trays made by himself from ordinary brown paper, put whilst wet on a wooden block of the required shape, and then when dry painted and varnished; their cost is almost nil, and to the tourist disliking travelling *impedimenta* they would be invaluable owing to their almost feather weight.

The chief attraction of the evening was a lantern exhibition, entitled

Glimpses of Picturesque Italy, by Mr. G. E. THOMPSON. To carry this out the windows had been blocked up with brown paper to keep out the sun, which was then shining in full vigour. This was Mr. Thompson's second visit to Italy with the camera, and resulted in a number of new places being brought before the Association that had not been seen before. Some three hundred views in all were taken, and the exhibition consisted of about half of these, and included Naples, Vesuvius, Capri, Amalfi, Venice, Milan, Pisa, &c. Many of them were of exceptional beauty and showed very high art in their conception. Mr. Thompson used quarter-plates throughout, which experience had taught him was the proper sized camera for a lengthened tour. His slides being all printed by contact, they showed every variety of colour—black to rich sienna brown, as most suited to each particular view; the latter tint, it was explained, being obtained by using the developer *cum grano salis*—Cowan's formula with a pinch of salt added. The lecturer enlivened the tour by an amusing and descriptive account of his travels in search of the picturesque, which was not the least enjoyable part of the evening's proceedings.

A very hearty vote of thanks to him and Mr. F. Evans for bringing and manipulating his lanterns brought the evening to a close at a late hour.

Correspondence.

Correspondents should never write on both sides of the paper.

JUNE MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE. — ON THE NON-SUCCESS OF THE DIFFERENT CONCOURS. — A PRIZE OF 1000 FRANCS OFFERED BY M. DAVANNE. — ENAMELLING PLATINUM PROOFS. — DEATH OF AN OLD AND ESTEEMED MEMBER. — AN INVITE FROM THE ENGLISH CONVENTION. — A NEW LENS. — TWO NEW APPLANATIC LENSES BY M. MARTIN.

The Photographic Society of France held their monthly meeting on Friday evening last, the 3rd instant, M. Peligot in the chair.

The Secretary informed the members that he was sorry to say that no one had come forward to dispute the prize of 2000 francs offered by "Le Ministre de l'Instruction Publique" for a progress in photographic lenses. The Committee proposed that the time should be prorogued until December, 1887.

The *concours* Gaillard, consisting of a prize of 500 francs for the best system of a film replacing glass, is under the same conditions—cannot find a laureate.

M. Bardy informed the Society that M. Davanne had offered a prize of 1000 francs to any one who can discover a sensitive surface for negatives so as to replace the gelatino-bromide of silver.

This *concours* is to be international.

M. Davanne, who is one of the old school, is grieved to see that at the present day no such beautiful, transparent negatives can be seen as in the old time of collodion and the silver bath; he therefore proposes this prize to incite the photographic genius of the numerous amateurs, as well as the profession, to discover a medium by which negatives can be obtained equal (or better, if possible) to the late collodion process. He asks: (1), Simplicity of preparation; (2), Sensibility of surface not unequal to the rapidity of the gelatino-bromide of silver process; (3), Solidity and firmness of surface.

These are the principal items that I was able to glean. No doubt the *concours* will be published ere long; I will then inform the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY. These notes will keep them on the alert, if adventure some of them will try a struggle for fame in the scientific tournament which will take place.

A communication was sent in as to a manner to enamel platinum proofs. The author says it is necessary, first of all, to eliminate all the iron salt which may remain in the fibres of the paper by means of a feeble solution of hydrochloric acid, then wash thoroughly. The print when dry is immersed in a feeble solution of gelatine until it is completely impregnated; it can now be enamelled by any of the known processes, and will have a far better appearance than if this preliminary immersion was not accomplished.

The Society received the sad news of the death of M. Bayard, one of the founders of the Photographic Society of France. M. Chardon gave the members biographical notes of the services which this eminent *collegue* had done for the advancement of photographic knowledge.

The Secretary informed the Society that he had received a letter from Mr. Heinrich Trinks, of the Photographic Convention to be held at Glasgow, inviting a deputation from the Photographic Society of France. The President and the bureau named Professor Stebbing to represent them at the Convention; he thanked the President and the members for the great honour which had been proposed—at any other moment, said he, he would have gladly acquiesced, but the well-known fact of the catastrophe which had lately befallen him, together with the lawsuits pending against the Insurance Companies, would be an excuse for his declining. Other members were requested, but their ignorance of the English language, or the short time allowed, compelled them to retire.

M. Balbreck presented a landscape lens, consisting of three glasses cemented together; it appears that with this lens a larger diaphragm can be used than with the well-known single actinic view lens. M. Balagny spoke highly of it, and exhibited a negative (12 x 8) which he obtained by its aid.

M. Adolphe Martin, the well-known *savant*, presented two new lenses to the Society, the curves of which had been calculated by himself—in fact, had been made under his supervision. No doubt the Committee will make a report upon them.

PROF. E. STEBBING.

59, Rue des Batignolles, Paris, June 5, 1887.

PRETENDED PHOTOGRAPHY IN NATURAL COLOURS.

To the Editors.

GENTLEMEN,—The unfounded nature of the pretensions of the Cellierier Syndicate to "Photography in Natural Colours" having been exposed, it might seem unnecessary to discuss the matter further but for the suggestion that their productions might be entitled to be called "Photographs in Colours," and that such a name would not be misleading. In reply to this suggestion I submit, first, that photographs coloured by the Cellierier or any similar process of hand painting are not "photographs in colours," and, second, that the expression photograph in colours is, and always has been, understood by the public to mean that the colours have been produced by photography and not by the painter; third, that therefore to call the Cellierier or any similar productions "photographs in colours" is just as much a misstatement and just as much calculated to mislead the public as the title they put forward, "Photography in Natural Colours."

1. In the Cellierier process the photograph is an ordinary autotype or carbon transparency. The application of the colours is a separate process, depending upon the judgment of the painter in selecting the colours and his skill in applying them to the places where he desires to produce his effects. The result is a coloured photograph, and no more a photograph in colours than a hand painted lithograph is a chromolithograph.

2. I suppose that there are few photographers of any lengthened experience to whom the remark has not been occasionally addressed by one of the public, "I suppose the next thing will be that you will be able to take photographs in colours." Whatever the reply may have been, the idea existing in the minds of both speaker and photographer has been that photographs in colours means pictures in which the monochrome of actual photography shall be substituted by a coloured image, not that a monochrome image is to be coloured by a painter, and this idea is a perfectly just one.

It happened some time ago (perhaps a year and a half or two years since) that a gentleman of my acquaintance, who had been connected with public companies, called upon me to ask my opinion respecting a process in which he thought of interesting himself, and which had been introduced to him as a process of taking photographs in natural colours. He obtained and sent me the specification (Cellierier's), and at our next interview I gave him my opinion, which is, and was, that to introduce such a process as photography in colours would be quite as unjustifiable as to supply cotton under the name of silk, or brass as gold. My friend, of course, replied that he would have nothing to do with such an affair. The process has, however, found investors or supporters who have not scrupled to bring it out with the misrepresentation that has justly been condemned in the photographic press.

"It must be true, it's in the papers," is an old saying which represents the feeling engendered in the public mind by statements, some quite recent, in journals claiming to be leading organs of public opinion, as to the new era said to be now instituted in photography by the discovery of processes for producing photographs in natural colours. It is not easy to convince the public of the fact that these statements, however they may conduce to the pecuniary interest of certain people, have not a vestige of truth in them. To the honour of the *Standard* among leading newspapers, it may be said that it is not amenable to the influences which can procure the insertion of paragraphs of the nature referred to. Will not the proprietors of other leading newspapers see the desirability of sifting such matters so far as their own columns are concerned, and of taking means to prevent for the future their influence being used for the purpose of disseminating misrepresentation for the benefit of commercial speculators?—I am, yours, &c., W. E. DEENHAM.

To the Editors.

GENTLEMEN,—In your article last week on "Photography in Natural Colours" you point out that the title is "misleading and therefore reprehensible," and you suggest that there is no objection to the title of "photographs in colours." I really think if the public is likely to be misled by the former, it will be equally so by the latter. The only title that would not be misleading surely is "process for colouring photographs."—I am, yours, &c., A. COWAN.

Photographic Club, June 15, 1887.

To the Editors.

GENTLEMEN,—Again we are brought face to face with the alleged fact that photography or photographs in colours is *un fait accompli*. It would be interesting if some statisticians would inform us the different periods

at which this is thrust upon the too credulous British public. As photography progresses so does the number of the so-called processes for the production of photographs in natural colours—in fact, in a far greater ratio. It is a growing shame that these Companies, and others, are allowed to advertise the fact that they are now able to produce *photographs* in natural colours. I mention the word photograph as you appear to think that it is not so misleading as “photography.” I really cannot see the difference; the one is as misleading as the other. A photograph I understand to mean the image, no matter what may support the image; and photographs in colours would infer that the image itself was produced chemically in colours from the object copied; and it is this which the present processes before the public are meant to convey, but in reality is not so. Not only do the general public suffer, but I have reason to believe that professional photographers are suffering from the results of this so-called colour photography, which is spreading far and wide. Sitters are waiting to see and hear more about this new discovery before having their portraits taken in the ordinary way. I imagine this to be the cause why many photographers with whom I have come in contact have had so few sitters as compared with formerly.—I am, yours, &c.,

J. B. B. WELLINGTON.

38, Fellows-road, South Hampstead, N.W., June 16, 1887.

[From a perusal of what we wrote last week and the correspondence arising therefrom, we perceive that the reconstructed title of the Syndicate, “Photographs in Colour,” is not sufficiently definite. We held it for the moment as being synonymous with *Coloured photographs*, which term not being capable of ambiguity we now substitute for that previously given, so far as concerns our own expression of opinion.—Eds.]

MEDALS.

To the Editors.

GENTLEMEN,—The letter of “An Exhibitor” is an interesting contribution. I believe medals might be dispensed with at exhibitions if detailed criticism of pictures in the journals could be guaranteed. A number of persons would rather be noticed unfavourably (but kindly) than not noticed at all.

“An Exhibitor’s” eighth correspondent, however, makes some remarks evidently referring to the Newcastle Society, and as the Hon. Secretary thereof, I would like to notice his final sentence, that about good management and confidence. His remarks, vague and unsatisfactory regarding my own work, I can pass over, merely noting that all my awards have been obtained in open, and, in most cases, keen competition. I should not personally value a “walk over,” but I can sympathise with a disappointed exhibitor, having often enough experienced similar sensations. I imagine this eighth correspondent, who talks of “our Society,” must be a member of the Council; if so, he lacks sincerity, or he would have turned up at our last meeting, when he might have done great service. Societies are managed by their Councils, elected annually by the members. If a member wishes to nominate certain officers, he can do so by letter to the Secretary, if he does not like to do so in open meeting. I think a change every year would be very desirable, but it is extremely difficult to get this carried out. I have now and then met with members like No. 8, and have endeavoured, sometimes with success, to get him on the Council in order to give him a chance; but when the opportunity has occurred, when some new departure has been desirable, the member has been conspicuous by his absence.

In conclusion, your readers may bear this in mind, that “Societies are very much what the members like to make them.”—I am, yours, &c.,

16, New Bridge-street, Newcastle-on-Tyne, June 12.

J. PIKE.

CAMERA BACKS AND OTHER MATTERS.

To the Editors.

GENTLEMEN,—I must apologise to Mr. Poirin for my oversight as to his camera back, which I had quite forgotten, though it is, as he says, in the 1885 ALMANAC, and I must have seen it when I made the camera which I sent for your inspection, whether I drew the idea from it, or, as I believe, had previously hit upon it myself. In any case, by universal custom, priority is decided by publication, and he must have the credit of having effectually barred any valid patent for a back with a closed bag. I should, perhaps, point out in the same connection, that the plan of pushing out the plates by the action of the sliding shutter had also been previously applied by Mr. Samuels to a repeating back with two compartments, so all I could in any case claim is the combination of the two ideas, which in my experience makes a very useful form of back with the special advantage that it cannot expose the same plate twice.

May I venture to add to your practical remarks on the use of gas in a recent issue, the suggestion that for all connections which do not require frequent moving, common “compo” gas pipe is both a cheap and convenient material, and may be easily jointed with short lengths of indiarubber as you suggest for glass?

With reference to the inaccurate measures mentioned by a recent correspondent, a pharmaceutical friend has pointed out that all measures used in dispensing must be examined and marked by a Government

inspector, and are thus guaranteed approximately accurate. I have such a two ounce measure before me as I write, from the York Glass Works, and marked V.R. Y.K. It is tall and slender, and the first two drachms are divided into minima, which is very convenient for mixing concentrated developers. The price is about 1s. 6d.

Mr. Drinkwater’s excellent paper on pyrogallol published in your last, was one of a sort of which we have only too few, and his suggestion as to the source of modern pyro was specially interesting. I should like, however, to understand exactly what he meant by calling sulphurous acid a restrainer. Of course excess of free sulphurous acid or acid sulphite in the pyro developer is not only a restrainer, but, like every other acid, completely stops development. But free acid and sulphites cannot exist in presence of free ammonia, and neutral sulphites, whether of potash, soda, or ammonia, are not known to have any restraining action. No doubt, theoretically, some change is constantly taking place in dissolved pyro, but I have not found either practical deterioration or restraining action from solutions preserved many months with acid potash sulphite, so long as the requisite quantity of ammonia was used to neutralise the free acid, while for convenience and accuracy of measurement the solution has greatly the advantage over dry pyro.—I am, yours, &c.,

HENRY R. PROCTER.

Tynemouth, June 13, 1887.

SMALL PLATES IN LARGE SLIDES.

To the Editors.

GENTLEMEN,—It is just possible you may think my experience worth publishing in the following matter:—I had been much troubled by the difficulty of always getting half-plates to fit into carriers for use in a whole-plate camera. I cut two spoiled negatives to the exact size required to fill up a whole-plate dark slide with a half-plate, put the two in together, and by means of the sliding front, shift the lens in focussing so as to cover quite sharply the part of the slide where the plate is, and find the plan works admirably.—I am, yours, &c.,

R. C. MACLEOD.

Bolney Vicarage, Hayward’s Heath, June 8, 1887.

DETERMINING THE TRUE FOCUS OF LENSES.

To the Editors.

GENTLEMEN,—Will you permit me to call attention to two errors in Mr. Lyonel Clark’s paper on *The Focus of Lenses*, as given in your issue of the 10th instant?

Equation (1) should be—

$$\frac{1}{B} + \frac{1}{A} = \frac{1}{F}$$

and in the second line of the following paragraph “A = 8” should read A = ∞.

I need make no apology, I think, to Mr. Clark for pointing out these errors as they are evidently merely clerical, and as such would not need correcting except for the sake of those of your readers who have not much confidence in their own knowledge of optics.

There is another method—also recently given by Mr. Traill Taylor—for finding the focus of a lens which Mr. Clark does not recount, and which I have found preferable to, because simpler than, the pinhole method. It is as follows:—With a pencil draw on the focussing screen two vertical lines; these may be placed anywhere, but should, for the sake of accuracy of the determination, especially in the case of long-focus lenses, be as far apart as possible without getting too close to the sides of the screen. Then, placing the camera on a board or a piece of paper laid on a table, focus some distant object—a flagstaff, chimney, or vertical corner of a building is convenient—on one of these lines and draw a line along one edge of the baseboard on the paper beneath it. Now swivel the camera till the same object is focussed on the other vertical line on the screen, and draw another line along the same edge of the baseboard. If now, with these two lines as sides, an isosceles triangle be completed, having its base equal to the distance between the two vertical lines on the screen, the length from the vertex of this triangle to the middle of its base is the true focus of the lens.

This method requires but one object—and it is not always easy to find two suitable objects which can be got into the field of view with any lens—there are no awkward measurements to be made in the camera, such as from pinhole to screen, the small amount of geometrical construction requisite is conducted with the convenience of an improvised drawing board, and no additional apparatus has to be fitted to the camera, so that it is, I think, in practice the simplest of any yet given, and withal it is theoretically correct.

Good things bear repetition, so, although it is not long since this method was fully explained by Mr. Taylor I have ventured to recall it while, by reason of Mr. Clark’s paper, the subject is fresh in our minds.

Mr. Clark’s view meter modification of the pinhole method is not, I fear, calculated to give very accurate results, as I have always found it very difficult to measure with any degree of certainty the distance of any object from the eye.—I am, yours, &c.,

Z. H. KINODON.

Old Charlton, Kent, June 15, 1887.

NEWTON'S RINGS.

To the Editors.

GENTLEMEN,—Can you or any of your readers inform me if the Newton's Rings, which are formed between the glass of the printing frame and that of the negative, are capable of leaving an impression on the prepared paper in the frame?

The colours produced by transmission being so much fainter than those by reflection, I should not have expected it; however, I have frequently found markings in the sky corresponding in position to rings seen by reflection.

—I am, yours, &c.,

M. D.

Bristol, June 9, 1887.

[Newton's rings do give a photographic impression, as we have proved many times.—EDS.]

THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—Photographers do not claim the negative as a right, nor do they allow that right to be claimed by the sitters. It has been the custom for photographers to preserve and retain the portrait negative, not for their own benefit only but for the benefit of their clients also, from whom an expressed wish that it be no longer retained would receive immediate attention.

I am an amateur of the old wet date, and this has been my experience of my professional friends, with some of whom I have been long intimate. They are good, generous men—men of strict honour.

Among professors of the art I find, however, that there are some who advance this foolish claim. To them I would say—Give the reasons for your claim in the numbered form 1, 2, 3, 4, &c., and by this means silence your opponents, or give them work to confute the statements advanced for the claim.

One correspondent writes, "That the sitter orders one dozen cabinet portraits with which he is supplied." "These were all he wanted and all he was promised;" an excellent reason for the operator's claim to the negative. Allow me to add that for these dozen of copies the photographer was paid 25s.; this sum was all he asked for, and he was promised no more.

What now about the negative? The glass and the film are undoubtedly the photographer's, and the impressed portrait on the film belongs as undoubtedly to the sitter—a joint partnership. A very simple arrangement or understanding between photographer and sitter would settle the matter, but without an arrangement or understanding honesty does not give the claim to the photographer.

The remarks of A. L. Steavenson, of Durham, I have noted. In him my fellow citizen has found another illustration of the truth of his statement that some minds are incapable of judging moral right and moral wrong.

"Use and Wont" has upset me—the word Edinburgh has caused a disagreeable moisture in the corners of my eyes.—I am, yours, &c.,

The Engineering Works, South-street, Newcastle-on-Tyne, Mac.

June 13, 1887.

To the Editors.

GENTLEMEN,—I am not a professional photographer, and don't expect to be, but I am certainly of opinion that unless a sitter agrees to buy the negative as a separate article, the photographer has a right to keep it, so long as he does not trespass on his client's rights by issuing copies from it without permission. Surely no one having a correct knowledge of the skill and labour entailed in the production of a good portrait negative can argue that it is amply paid for out of the profit on a dozen or so of copies, even though a little extra charge is made for the first lot. An adult customer has almost invariably at least two negatives taken, and as for children and babies—well, the average experience is too harrowing to relate. I have frequently walked into studios, when the artist has been engaged on a lively young specimen, and patiently waited in the anteroom listening to the ridiculous cooing, whistling, horse-driving sounds, and urgent appeals from the operator to his sitter (or rather kicker) to "watch for dickie-bird coming," until my mind has wandered to a certain placard exhibited by a German photographer for the enlightenment of his English visitors, "Babies instantly executed here;" and I have thought what a blessing it would be if the creature could be executed for a few seconds to give the exasperated operator a chance of uncapping his lens without spoiling half a dozen of his "baby plates," to say nothing of his time, which, of course, is no object, though it would be to a mechanic at so much per hour.

Then came the retouching, printing, and sending of proofs, booking, &c., all of which are mere trifles compared with the handsome profit on the finished prints.

Apart from this, I fail to see the public grievance caused by the retention of the negative. I can see plainly that the surrender of it is likely to be prejudicial to the photographer, and in many cases even to the sitter. I have known several instances where it has been bought and

willingly paid for, but a few years, or even only a few months after, it has turned up so scratched, broken or otherwise damaged, on the decease of the person represented, that the only decent copy obtainable has been a somewhat costly one worked up in colours, whereas the photographer would have taken more care of it. As regards the other point, there is no doubt the photographer relies to some extent on repeat orders; otherwise it would be open to any one to get half a dozen or a dozen prints, demand the negative, send it to a professional printer, and get any quantity of, say, unmounted cabinet prints at about 1d. each, and mount them at home. This would be very nice for a bazaar committee, for instance, who wished to make money by selling portraits of a pet local celebrity, and of course quite fair to the painstaking professional who supplied the cliché.

What shall he do in the case of a group? Every member of that group has a perfect right to his own part of the negative. Of course it would have to be nicely cut up with a diamond, and woe betide him if in cutting out a front row he encroaches upon the rights of a back-row member, I am afraid some of the heads would get legs and arms that did not belong to them, while others would be mere Fatimas, or "bodyless beauties."

Next time I have any lithographing done, I shall demand the stone; it will only weigh thirty or forty pounds, and the lithographer has no right to keep any impression that refers only to myself. Anyway, if I cannot lug the stone away, I will have the transfer, as it is paid for in the price.—I am, yours, &c.,

A. A. PEARSON.

Leeds, June 15, 1887.

To the Editors.

GENTLEMEN,—The lady amateur, "Millie's" pathetic appeal against her negative (not herself) being "labelled, registered, and stored to criminal bondage" (poor negative!), will in itself almost turn the stony hearts of the profession to her way of thinking. Future orders for one dozen cartes will be accompanied by the negative, which in ninety-nine cases the client would rather not have, preferring it being carefully and tenderly cared for by the photographer, knowing in years to come, when memories become valuable, they can with certain have a further supply.

"Millie" having asked herself why the negative should be retained, "for which they have been handsomely paid" (not always), could with advantage further ask herself, Was the order for pictures only, or pictures and negative? Did she ever see a photographer's price list mention anything other than "cartes-de-visite and cabinets" at so much per dozen? I consider the negative as much the property of the photographer as his lens that threw the image. "Millie" further considers and suggests a Parliamentary Debating Society shall fight the battle. Should they decide amongst themselves by a large majority on division against the photographic artist then "after copies" business is doomed. We shall have an army of gentlemen willing to print for practice and a small consideration. People will walk about with their negatives as many do with their own last in search of the cheapest printer or bootmaker.

Why "Millie" should designate sitters as "ladies" and "gentlemen," photographers, "man" and "men," "of nothing further known than their professional names," &c., is best known to herself. To such "men" she should not again sit. Far better buy her own plates and get a "gentleman" amateur to make negatives for her. How nice this would be.—I am, yours, &c.,

T. COX.

50, Cumming-street, Pentonville, N.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Required, a single-view lens by good maker, for plate 10×8, in exchange for cabinet burnisher, nearly new.—Address, A. FERRARI, Photographer, Wood-street, High Barnet.

Will exchange carved walnut show case, cost over £20, for portable 12×10 camera and double dark slides, and tripod stand for same.—Address, CAMPBELL, 4, Mulgrave-road, Sutton, Surrey.

Will exchange a good eleven-inch bar burnisher (new and never been used) for a good rectilinear lens. Difference adjusted.—Address, CHAS. WM. APPLETON, Photographic Engineer, Maperton-road, Bradford.

I will exchange a fine gilt show frame (takes twelve cartes and six cabinets), with protecting outer frame, in good condition, for cornet, banjo, mandolin, zither, or old double-bass.—Address, RAYMENT, Aldermaston, Egham.

Wanted, quarter or half wet plate repeating back camera, also Victoria camera and lenses. Exchange, plain cloth background, outdoor ditto, 12×10 single lens, lectern, &c.—Address, PHOTOGRAPHIC COMPANY, King-street, Weymouth.

A Ross' quarter-plate portrait lens, Vogel's wide-angle 12×10, Dallmeyer's 2n, and whole-plate French lens. Any of the above in exchange for a wet-plate camera to take two quarter-plates on half-plate in two moves, with two dark slides.—Address, J. SALT, 14, New Arcade, Sunderland.

Wanted, a 12x10 bellows camera, lens, and stand, quarter or half-plate Lancaster's International or other light set, also a good magic lantern. Offered, astronomical telescope, gold watch, stereoscopic camera and lenses, and other photographic goods in exchange.—Address, A. BUCKNALL, 7, Bellevue, Clifton, Bristol.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

John Stuart, 120, Buchanan-street, Glasgow.—Two photographs of Rev. J. McGregor.

A. B.—To preserve the gelatine add a little alcohol or thymol.

A. HOPKINS AND J. PARKINSON.—Inadmissible. See conditions.

A. T. D. BERRINGTON.—If you ever come to London we shall have pleasure in showing you the camera.

G. S. T.—It is possible with an orthochromatic plate to photograph the beacon fire. The exposure must depend upon the aperture of the lens employed.

HALF PLATE, No. 2.—No hope of making a really good negative of your over exposed one. Make a transparency from it, and from that make another and more intense negative.

S. S. S.—1. A shock after exposure is completed will not affect the sharpness. —2. You may call your studio the Royal, but you must not use the royal arms. —3. Send the lens and we will examine it.

R. C. MACLEOD.—1. If the solution has become yellow it is useless, but the zinc treatment will restore it to working order if applied as recommended by the writer of the article. —2. The plan is not applicable to pyrogallie developer.

B. O.—Saxe paper may be obtained of any of the dealers in photographic materials. If they do not keep it in stock they will procure it for you. They will quote you a price. Unless we knew the purpose for which it is to be used it is impossible to say if it will require any preparation before coating.

W. F. TIMPERLEY.—If you act as your own patent agent the cost of the provisional protection for nine months will be one pound. Upon a further payment of three pounds within the nine months you will secure a patent for four years. One patent will secure all the parts of the invention. Registration is useless.

A.—The paper should be sensitised on a plain solution of nitrate of silver. The strength must depend upon the amount of chloride with which the albumen is salted. Unless we knew this we could not say the strength required. Your best plan will be to sensitise three sheets, one on a forty, one on a fifty, and the third on a sixty-grain bath, and see which produces the best results when printed.

TOM writes as follows: "Say I have an object sixteen feet by less in width to photograph on—well, say a whole-plate, using a lens thirteen inches equivalent focus, is there a rule to tell me the number of feet distance required between the lens and the object? If there is, kindly explain."—If our correspondent will refer to the Table of Enlargement and Reduction given in the ALMANAC he will obtain what he requires.

INQUIRER writes: "I have had the misfortune to leave several printing frames out of doors in a drenching rain; the consequence is the wet got to the negatives and has produced silver stains, although the negatives were varnished; they are now quite worthless. Can you tell me what to do with them, for they are valuable, and I do not want to lose them if possible?"—We fear the case is hopeless. If a weak solution of cyanide of potassium will not remove the stains the negatives may be considered as permanently ruined.

G. F. ABCOCK says: "I wish to enlarge with eight-inch condenser from half-plate to 10x8, that is, to get an enlarged negative on a dry plate to print from. Can you give me any idea of the exposure necessary, also the development? My lantern is one of three wicks."—Without knowing the actinic power of the light or the sensitiveness of the plates it is impossible to give any idea of the exposure required. The best plan will be to make one or two trial exposures on small plates of the same sensibility. The ordinary developer used for negatives will do quite well.

W. T. Z. writes: "Will you kindly give me, in your 'Answers to Correspondents,' a formula for getting cold grey tones on ready-sensitised paper? The paper I have been using is —'s sensitised paper, and I can get nothing but brown tones with it, which I very much object to. The bath I have been using has been the lime bath or acetate.'—As a rule, the ready-sensitised papers are not well adapted for cold grey tones. The best plan of obtaining them will be for our correspondent to sensitise the paper for himself, using a moderately strong bath for the purpose; then, with the lime bath or the carbonate of soda bath, no difficulty will be experienced in securing cold tones.

W. E. METHVEN says: "I see in this week's JOURNAL a reply to 'W. A. C.' with reference to snail marks on gelatine plates. You say there is no way to get rid of these when they exist, as they are due to the manufacture. Of this I am aware. I have made batch after batch of plates and cannot get rid of these markings, which are always more or less strongly shown. They are particularly obnoxious in portraiture with a plain background. Can you tell me to what these snail marks are due? I have tried everything in reason in the way of filtration. Is it due to any particular make of gelatine? I have spoken to several plate makers, professional and amateur; some did not even know of their existence, others suggested different expedients as remedy, but all to no purpose. Can you enlighten me through your 'Answers to Correspondents?'"—Some samples of gelatine are more prone to these markings than others. We advise our correspondent to try a sample from another source than that from which he has drawn his previous supplies.

FIXATION says: "I should like to know the cause of spots on enclosed prints. They have been, to my way of thinking, most carefully manipulated, the following being the process:—After exposure they were washed in five or six changes of water, in the first two of which they did not remain more than a minute or two, and they were whirled round and round the dish all the time, the total time for all these washings being about thirty minutes. After this they were toned, some in the carbonate bath and some in the tungstate bath, accurately prepared from the standard formulae. When toned (and it was at this point that most of the spots were first discernible) they were again washed for a few minutes in two or three changes of water, and then fixed in hypo, four ounces to the pint of water, just enough liquid ammonia being added to be easily smelled, that is, to make the solution smell of it. The amount of the latter might be in excess of that quantity usually recommended, but there was not more than half a teaspoonful to the pint, if that much. In the fixing bath they were kept for fifteen minutes, the dish being rocked from side to side all the time, and the greatest care taken that no two should stick together. Upon their removal from this bath they were washed for twenty-four hours in several changes of water; for the first quarter of an hour they were kept in constant motion, and were not allowed to stick together at all. I have never noticed this defect when using the acetate bath nor before I purchased the sample of gold chloride I am now using, and which is the best, or, rather, the dearest. An answer in the JOURNAL will greatly oblige."—The spots have all the appearance of being caused by air-bubbles sticking to them while in the fixing bath, but if they make their appearance before they are fixed it is clear this is not the cause; therefore the only suggestion we can make is that the spots arise from air-bells while in the toning bath. We do not think the chloride of gold is at fault.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—On Tuesday, June 21, this Society will take part in the London Photographic Societies' Jubilee Excursion to Watford. Train: Euston, thirty-five minutes past ten; Willesden, fifty-four minutes past ten.

RECEIVED.—*Pictures from Life in Field and Fen*, by P. H. Emerson, B.A., M.B., will be noticed next week. Also received Price Lists of the various manufactures of Morgan & Kidd; Catalogues of James Swift & Son, and of Joseph Levi & Co., opticians.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, June 22, 1887, will be *Aids to Exposure*. Saturday outing at Waltham. Train from Liverpool-street at fifteen minutes past two. June 21, amalgamated Club and Society outing at Watford. Train from Euston at ten minutes past ten.

FROM M. Paul Nadar, of Paris, we have received an interesting photograph of the ruins of the Opéra Conique, which was taken immediately after the conflagration. The picture is one of two hundred which Mr. Nadar has obtained in a few hours with the ingenious Eastman-Walker roll holder, using their films.

NORTH SURREY.—At the next meeting of the North Surrey Photographic Society special novelties are to be introduced. Members and non-members are invited to bring their photographic outfits ready for field work, for the purpose of comparing and discussing the merits and demerits of their apparatus. The meeting will be held at the Greyhound Hotel, Dulwich, on Wednesday, June 22, at eight p.m.

* * * Owing to pressure on our columns we have been compelled to hold over several articles, including an account of Richmond's Instantaneous Shutter.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1416. VOL. XXXIV.—JUNE 24, 1887.

COLLODION *VERSUS* GELATINE.

At the meeting of the Photographic Society of France, as will be seen from our French correspondent's communication last week, M. Davanne has offered a prize of a thousand francs to any one who will devise a method of producing "sensitive surfaces" to replace gelatino-bromide of silver and which will at the same time yield results equal to collodion with the silver bath. Full details of the conditions are not yet published, but the principal ones are understood to be—"first, simplicity of preparation; second, sensibility of surface not unequal to the rapidity of the gelatino-bromide process; third, solidity of surface." M. Davanne laments to see that at the present time no such beautiful, clear, transparent negatives are being taken as used to be produced by the wet collodion process. Hence his liberal offer of a prize for another and better process.

Is it a fact, however, that the gelatino-bromide process does not yield, or is not capable of yielding, results quite equal to collodion? Some we know will answer emphatically "No!" while others will as positively say "Yes!" That there is a wide difference in the appearance of the negatives by the two processes cannot be denied, but the real test of the quality of any negative is the excellence of the print it will yield. Cannot as good impressions be obtained from gelatino-bromide negatives as from collodion? If not, it is clear that photography has degenerated, to some extent at least, since the general employment of dry plates in place of wet; certainly, in the opinion of the giver of the prize, it has in France. We know many photographers of the old school in this country who, like M. Davanne, still sigh for the rich, brilliant negatives of old, with their clear shadows and vigorous lights, which, they say, cannot be obtained with dry plates. On the other hand, we are aware that a large majority of modern artists, whose experience with the wet process is but limited, or who, perhaps, never worked it at all, declare that far better negatives are now being made with dry plates than were possible with wet. Therefore it is clear that negatives by the two processes should be judged by a different standard. And why should they not?

At one time it was not unusual to see in advertisements that certain makes of plates would render negatives equal to wet collodion; one rarely sees such announcements now. It is quite within the bounds of possibility, if the collodion process were only now being introduced as a new one, that the claim might be made for it that it would produce as good results as gelatine. Be that as it may, it is clear that the two processes should not be compared from the same standpoint.

A good collodion negative, when placed upon white paper, has perfectly clear glass for the deepest shadows, with the lights more or less intense according to the density of the image,

whereas the shadows in the usual run of gelatine negatives when similarly tested are seen to be, to a certain extent, veiled. What, it may be here mentioned, might be considered clear shadows in a gelatine image would be looked upon as fogged in a collodion one. That veiled shadows were produced with bath plates, and perfectly clear ones are obtainable with dry ones, cannot be denied, but in either case it was, and is, the exception and not the rule.

It is said that gelatine negatives—we are now referring to portraiture—require far more retouching than did collodion, before they can be placed in the hands of the printer. Hence they become more costly. Much greater importance, as most know, is now attached to retouching than formerly, but it is a question whether this arises so much from the inferiority of the negatives themselves as from the higher finish demanded by the sitters. However, there can be little doubt that more time is now expended upon working up gelatine negatives than was bestowed upon those made with collodion.

Whatever may be the opinion amongst the most conservative of professional photographers, we find, as a matter of fact, that they, as a rule, have abandoned collodion for both portrait and landscape work. Are we to assume that they have done this simply on account of the convenience of working and the exalted sensitiveness of the plates, knowing all the time that the quality of their work would prove inferior in the end? We think not. Our leading artists, whether in portraits or landscapes, produce as good printing negatives on gelatine as they did on collodion, while a large majority of those who only produced mediocre results with wet plates are now doing far better work with dry—a circumstance scarcely to be wondered at. With amateurs, too, the same holds good. The veterans in collodion have all adopted gelatine, and are securing equally as good results by the change with a far greater variety of them.

The gelatino-bromide and the wet collodion processes each have their strong and their weak points, as every one is fully aware, and if any new process can be devised which will combine all the good qualities of each—while eliminating the bad ones—a great advance in photography will be secured. Therefore M. Davanne is to be commended for his liberality in offering a prize for what many photographers, not only in France but everywhere else, have long been sighing for, namely, a dry process which will yield negatives with gelatine rapidity and collodion qualities. Let us hope that such a process will in the end be forthcoming.

CYCLING is now so much a part of outdoor photographic work that the velocipedist almost deserves a corner for himself. The tricycle is naturally the favourite, though we have seen not a few pair-wheels

evidently equipped for action photographic; but, whichever is selected, the one great question to the amateur who, for dark room purposes, has, perhaps, robbed his premises of the only spare corner the powers that be would consent to, is, "Where is the cycle to be put?" We are pleased to find that with a knowledge of the shifts to which the owners of the wheeled horse are so often put, a well-known firm has devised a portable house or shed ready for instant erection in any place provided that a bare wall and a vacant space a few feet square be available.

THE *Conversazione* of the Royal Society, held on the 8th instant, was a great success, and amongst not the least attractive of the exhibits, those belonging to the department of photography must undoubtedly be placed. Captain Abney's mode of illustrating the production of sunset colours by atmospheric absorption, though not exactly photographic, is yet interesting to photographers from the fact of the familiar "hypo" being the main agent in the experiment. A solution of this salt is made, sulphuric acid added, and a strong light sent through the liquid. A gradual precipitation of sulphur takes place, and according to the size of the particles so is the light of the emergent beam modified. The size of these particles is such as to scatter the rays from the blue end of the spectrum from the light received by the vessel, and to permit mainly the red ones only to pass through.

THE usual "Visitation" at Greenwich took place a little while ago, and as will be perceived from our report of the visitation in our issue for last week, a large share of the interest attaching to the report just issued centres upon matters photographic.

LAST year ought to be looked upon as above the average from a photographic standpoint, at any rate judging by the amount of bright sunshine; for we learn that the indications of Campbell's recorder gave a number of hours above the average of the last nine years, the sun having been brightly shining during twelve hundred and twenty-eight hours, which gave a ratio of twenty-seven hours' sunlight for every hundred hours the sun was above the horizon.

THE question of measurements above adverted to is one of very great importance, and it was discussed with some amount of heat at the last meeting of the Royal Astronomical Society. Professor Pritchard read a paper on the parallax of a certain star, as measured from photographs, three hundred and thirty photographs having been taken, and thirty thousand measurements made from the star images upon them. Mr. Ranyard took exception to the possibility of such exactitude being obtained from photographs, although he withdrew a previous description he had previously given of a magnified star image as like a heap of shingle. The opinion of the meeting seemed to be in favour of the accuracy of the measurements that could be made from photographic images.

AT the same meeting, photographs of the solar corona taken during an eclipse formed the subject of an interesting discussion, and they were utilised in an argument against a certain theory in connection with the corona, some of the later eclipse photographs being stated to combat Professor Hastings's theory that the corona may be accounted for as a diffraction phenomenon.

IN the brief study of the alkaline carbonates which we wrote a few weeks ago, we naturally omitted many points interesting from a chemical or a photographic standpoint, but amongst the impurities to be found with the sodium salt we may mention that, according to Herr E. Mylius, "hypo" is sometimes met with, an impurity which we need scarcely point out might lead to some confusion in developing operations.

IN a recent issue of *Comptes Rendus* there are a number of interesting analytical remarks upon the behaviour of the sulphites which were the means of assisting in devising an easy method of qualitative analysis. Thus, sulphite of soda solution is strongly alkaline to litmus paper, yet upon adding to it barium chloride, which

does not change the colour of litmus, the liquid is seen to be perfectly neutral to test paper, sulphite of barytes and chloride of the alkali being produced. If an alkaline bisulphite be treated with the above chloride the sulphite of the alkali is again produced, and the remainder of the sulphurous acid is set free in the solution. "Hence," says the writer, M. A. Villiers, "it results that if we treat with chloride of barium a mixture of an alkaline sulphite and bisulphite, a mixture which is distinctly alkaline to test paper even when the proportion of neutral sulphite is small, the solution becomes acid after the addition of the chloride of barium."

Now, although the price of sulphite of soda is above that of hypo, it is still a fact that a proportion of the former, larger or smaller according to circumstances, may be found in the latter salt. The above very interesting reactions show how the presence of this foreign salt may be shown. If the mixture of salts be alkaline it is to be treated with hydrochloric acid until no change is shown upon litmus, and then precipitated with the barium salt. The liquid will become acid and contain sulphurous acid.

THE APPROACHING CONVENTION.

FROM what we learn, the Glasgow Convention, which opens its week's *séance* on the 4th of July, is destined to be highly successful.

On the evening of the day mentioned, the proceedings will be opened by the Lord Provost of Glasgow. From the subjoined list it will be seen that excursions have been arranged with great skill, and that these embrace the choice artistic and historical parts of Scotland, at fares surprisingly low. Roughly speaking, the days are to be devoted to sight-seeing, and the evenings to the scientific and literary department of the Convention. Hotels, postal, and telegraphic communications have all been arranged by the energetic Local Committee. Those desirous of details other than we here subjoin should apply to Mr. J. J. Briginshaw, 128, Southwark-street, London, S.E.

SYNOPSIS OF THE WEEK'S PROCEEDINGS.

MONDAY, JULY 4.

Conversazione at 7.30 o'clock.

The proceedings will be opened by the Hon. the Lord Provost of Glasgow.

TUESDAY, JULY 5.

Excursion to the Falls of Clyde, in charge of Mr. Geo. Bell.

Excursion to the Trossachs, in charge of Mr. T. N. Armstrong.

Evening meeting at 7.30 o'clock.

WEDNESDAY, JULY 6.

Excursion to Loch Lomond and Loch Lomg, in charge of Mr. John Stuart.

Excursion to the Yacht Regatta at Largs (by special steamer), in charge of Mr. George Mason.

Evening meeting at 7.30 o'clock.

THURSDAY, JULY 7.

Excursion to Tarbert, Loch Fyne, by steamer "Columba," in charge of Mr. Wm. Lang, jun.

A group of the members will be photographed at Tarbert by Mr. John Stuart.

No evening meeting.

FRIDAY, JULY 8.

Excursion to Edinburgh. On arrival at Edinburgh the party will be taken in charge by the following Edinburgh friends:—Mr. James Oughton, Mr. William Crooke, and Mr. J. M. Turnbull.

Evening meeting at 7.30 o'clock.

SATURDAY, JULY 9.

A photograph will be taken of a group of the members at 10 o'clock, in Kelvingrove Park, West End.

Meeting of the Committee at 11.30 in the Convention Rooms.

DETAILS OF EXCURSIONS.

TUESDAY, JULY 5.

1.—To the Falls of Clyde, via Hamilton (in charge of Mr. George Bell).—By train, leaving Central Station 7.55, to Hamilton; thence by coach, driving about thirteen miles, to the Falls. Returning from Hamilton at 5.20; arriving back in Glasgow at six o'clock. Fare, for the trip, about 5s. or 6s. Driving from Hamilton, the party passes through

the district called the "Orchard of Scotland." The main points of interest on the drive are Camusnethan House, Garrison Bridge, Dalsert Village and House, Maidslie Castle, Milton Lockhart, Ruins of Craignethan Castle, the Tillietudlem of *Old Mortality*. The Falls are three in number—Stoneybiers, Cora, and Bonnington; these will fully and pleasantly occupy the day, presenting many fine views to the camera.

2.—*To the Trossachs, via Aberfoyle (in charge of Mr. T. N. Armstrong).*—By train, leaving Queen-street Station, at 8.10, to Aberfoyle; thence by coach, driving about five miles, to Trossachs and Loch Katrine. Returning from Aberfoyle at 3.45; arriving back in Glasgow at 5.30. Return fare to Aberfoyle, 4s. 6d.; coach extra. The party will have several hours to spend among the magnificent scenery at the Trossachs and Loch Katrine. Those who do not wish to go to the Trossachs may walk from Aberfoyle to Loch Ard, the scenery of which is very fine. Boats may be hired on the Loch, or the excursionists may walk round the Loch side. The whole distance round the Loch is twelve or thirteen miles. Most of the stirring incidents in Scott's *Rob Roy* and *Waverley* are represented as having occurred at Aberfoyle and Loch Ard side: as Bailie Nicol Jarvie's encounter with the Highland gillie, the tree where he was suspended in mid-air, &c. If the party should divide at Aberfoyle, some for the Trossachs and some for Loch Ard, they will reunite at Aberfoyle for return to Glasgow.

WEDNESDAY, JULY 6.

1.—*To Loch Lomond and Loch Long (in charge of Mr. John Stuart).*—By train, leaving Queen-street Station at eight a.m., to Balloch Pier on Loch Lomond, returning from Arrocher by Loch Long at 2.30, arriving back in Glasgow by Craigondoran to Queen-street Station at seven o'clock. Fare, for the trip, about 7s. The railway to Balloch passes Dumbarton Rock and Castle. The steamer from Balloch sails up Loch Lomond, through the magnificent straits of Balmaha to Luss and Tarbet. Those who wish may leave the steamer at Luss, and walk by the Loch shore to Tarbet, a distance of seven miles. From Tarbet, on Loch Lomond, the party will walk or drive a mile and a half to Arrocher, on Loch Long. This is a fine road, through a lovely and spacious glen. From the Tarbet end of this glen, there is a fine view of "Ben Lomond," and from the Arrocher end the best view of the "Cobbler." The scenery on these two lochs is as grand as any in the world, being a continuous panorama of wooded hill, grassy slope, mountain peak, and precipice. Coming back, the steamer passes through the delightful shore scenery of the Firth of Clyde.

2.—*Excursion by Special Steamer to witness Yacht Regatta at Largs (in charge of Mr. George Mason).*—By train leaving St. Enoch Station at 8.10 to Prince's Pier, Greenock, embarking there in steamer, and sailing to Largs, returning same way, from Prince's Pier at five o'clock, arriving back in Glasgow at 5.50. Fare for the trip, according to number of party, 7s. to 10s. The conductor of the party will fix time and place for going ashore to dine.

THURSDAY, JULY 7.

Excursion by Steamer "Columba" to Tarbert, Loch Fyne (in charge of Mr. William Lang, jun.).—Steamer leaves Glasgow Bridge at seven o'clock, or parties may take the train leaving St. Enoch Station at eight for Greenock, and join the steamer at Prince's Pier. The steamer goes by Kilm, Dunoon, Innellan, Rothesay, and Kyles of Bute, to Tarbert, returning at 1.20, and arriving back in Glasgow with steamer at seven, or by train from Greenock at six o'clock. This excursion is pretty much a whole day's sail—from Glasgow to Tarbert and back, about one hundred and sixty miles—on a favourite and swift saloon steamer, viewing the charming scenery of the Clyde, and spending two hours at the delightfully interesting fishing village of Tarbert. Fares for the trips, 6s.; or including breakfast, dinner, and tea, 12s. This being the only excursion to-day, it has been suggested that a suitable opportunity might be found at Tarbert for photographing a group of the members; arrangements for this purpose have been made with Mr. John Stuart, who will take a photograph of the group on landing at Tarbert.

FRIDAY, JULY 8.

Excursion to Edinburgh, leaving Queen-street Station at 8.45, returning from Edinburgh at five, and arriving back in Glasgow at 6.15. Return fare, 4s.

Offices of the Convention.—London: 128, Southwark-street, S.E.; Glasgow: The Institute of the Fine Arts, 175, Sauchiehall-street.

Railway Stations.—Caledonian Railway, Central Station, Gordon-street; Glasgow and South-Western Railway, St. Enoch-square; North British, Queen-street. All within five minutes' walk of the Convention Rooms.

The Exhibition will be held within the Institute of the Fine Arts, 175, Sauchiehall-street, and will be open daily.

Public Works and Factories.—Should any of the members wish to visit Public Works or Factories, this can be arranged for by giving notice to the Local Secretary.

A list of members attending the Convention will be posted on the Notice Board in the Office and Meeting Rooms. To facilitate the preparation of this list members are requested, on their arrival in Glasgow, to enter their names and where staying on the list at the Secretary's Office. It is hoped that many of the members will find it convenient to be accom-

panied by their lady friends to the opening meeting and to all the excursions.

LIST OF HOTELS.

St. Enoch Station Hotel.—Single bedroom and attendance, 2s. 6d. to 4s.; double ditto, 3s. 6d. to 6s.; breakfast, 2s. to 3s.

Central Station Hotel.—Single bedroom and attendance, 2s. 6d. to 5s.; double ditto, 5s. to 7s.; breakfast, 2s. to 3s.

The Bath Hotel, 152, Bath-street.—Single bedroom and attendance, 4s.; double ditto, 7s. to 8s.; breakfast, 1s. 6d. to 3s.

Philp's Cockburn Hotel, 141, Bath-street.—Bedroom and attendance, 2s. 6d. to 3s. 6d.; breakfast, 1s. 6d. to 2s. 6d.

Alexandra Hotel, 118, Bath-street.—Single bedroom and attendance, 2s. 6d. to 3s.; double ditto, 3s. to 4s.; breakfast, 1s. 6d. to 2s. 6d.

Cranston's Waverley Temperance Hotel, 172, Sauchiehall-street.—Single bedroom, one person, 1s. 6d.; two persons, 2s.; double ditto, two persons, 2s. 6d.; more than two persons, 1s. each; boots and service, each person, 1s.; breakfast, 1s. 3d. to 2s.

The two Station Hotels are five minutes' walk of Convention Rooms, all the others are close by the Rooms.

THE MANCHESTER EXHIBITION.

II.

We have alluded to Daguerreotypes as being present in the Exhibition. In connection with these there are several engravings possessing so much merit as to have elicited from a competent judge a doubt as to whether anything superior had been produced in modern times even by the most approved photo-engraving process. We may here observe, for the benefit of any reader who may be unacquainted with what was done in former times, that soon after Daguerre's process had been perfected, a great desire was felt to multiply them, for each picture by that process was unique and incapable of being reproduced save by copying with the camera. Strenuous efforts were made to get them etched under such a condition of surface as to hold ink, and ingenious almost beyond measure were the methods tried and adopted.

Through the labours of scientists abroad and at home, including the present Justice, Sir W. Grove, F.R.S., noted in those days as one of our foremost electricians, the problem was solved, and the Daguerreotype plate by being made the anode in an electrical circuit was engraved. The specimens now exhibited in Manchester are, as we have said, exquisitely fine, and their value is enhanced by the knowledge that they were at the time they were issued (about 1843) commercial productions. Whether they were engraved by the process of Grove or of Fizeau is unknown.

These desirous of seeing the earliest work executed by the collodion-bromide emulsion process cannot help being greatly interested in some prints by B. J. Sayce, of Liverpool, lent by that gentleman. Magnesium light portraits taken by A. Brothers in 1864; the first microscopic photographs taken by J. B. Dancer; glass positives taken in 1851; old photo-engravings by Placet; examples of early combination printing by Brothers in 1862; with wax paper negatives by Talbot and others; even burnt-in ceramics of an early period; these and many other invaluable records of a fast passing epoch in photographic history are all to be found in this rich collection.

When his Royal Highness the Prince of Wales was passing through the photographic department, his eye caught an old photograph which had been taken of the Queen and her cortege during the Art Treasures Exhibition in 1857. He was greatly interested in it, and requested to have a copy of the picture if it were possible. This Mr. Brothers promised should be supplied, a second one from the original negative being still in his possession. But we shall in this Exhibition for a time leave the "Ancient" and descend to the "Modern," and *Place aux Dames*.

Lady Roscoe seems to have in her the making of a high class photographer, and because of this we will point out certain defects in her technically excellent exhibits. In every one we saw the figures are large and pronounced, as they should be in carrying out her idea of illustrating photographically the *North Lancashire Industries*. But the defect is this, these figures are one and all ungracefully posed, most, if not all, of them staring into the camera, before which they are striking attitudes as if imbued with the idea that they were being photographed and that it behoved them to gaze steadily into the lens. If Lady Roscoe would once more go over the same ground and take these industrials by a snap shot when they were unaware

of her intention, a much better series of pictures would be the result, and her ladyship would ascend from being a mere photographer to the higher position of a real photographic artist.

Mrs. Main has three frames of views. Those taken in the Engandine have a lower tone than is desirable for public exhibition. This applies also to her three views from the Nadelhorn; but we know the reason. She has unwisely placed the prints in optical contact with the glass by which they are covered, and this causes a serious degradation of the tone, which is not objectionable when pictures are being examined by a good light at a parlour table, but not so when suspended on the walls of a public exhibition. This lady's frame of frost-covered trees are better in this respect.

Mrs. A. Green shows a frame of portraits, concerning which it is enough here to say that they fairly maintain their own amid a number of fine photographs.

Not so large in dimensions as numerically, the Autotype Company are extensive exhibitors. Whether it arises from the hanging or from the selection of the subjects exhibited, we have not previously been so much impressed with the real merits of their works, which, undoubtedly, add greatly to the importance of the Manchester display.

ECHOES FROM THE SOCIETIES.

My "Echoes" have been so long silent that I find some difficulty in again rousing them and in picking up the dropped thread of my weekly notes. I shall therefore have to glance briefly at the most important matters that have appeared before the Societies since my last, and bring myself as rapidly as possible "up to date."

First, I notice the proposed alteration of the Photographic Society's Standard of Diaphragms, which was brought before the Society, but which is now, I hope, a thing of the past. I had nearly written my own private protest against the proposed change at the time, but forbore, partly because the Parent Society is not over ready to take advice from outside sources, especially when good and sensible as mine must undoubtedly have been, but chiefly because I had sufficient faith in, at any rate, the "rank and file" of the Society to believe that they—the voting strength—had sense enough to prevent them stultifying themselves by undoing their own work when scarcely yet given to the world, and that at the mere suggestion of an individual.

We need not wade through the extensive and learned arguments delivered in print and at the meeting of the Society as to which is the more convenient number to manipulate, four or the square root of ten, or consider which looks most elegant as a unit, $\frac{f}{4}$ or $\frac{f}{\sqrt{10}}$,

because I do not suppose one photographer in a thousand would ever take the trouble to juggle with either in an attempt at calculation, and I question whether one in a hundred would know how to proceed if he were compelled to do so in order to save his life. So far as the unit of the standard is concerned it is, to the million, a matter of the supremest indifference; the optician marks the stops according to the U. S. value, the photographer does the rest *by table*; in fact, the basis of the standard is practically nothing, any number will work theoretically as the unit of a standard, but the most useful unit will not ensure the standard being recognised. Yet, forsooth! when the representative photographic society of Great Britain, after much labour, proposes such a standard, and by reason of its supposed representative character manages to get that standard largely adopted and recognised both at home and abroad, they are quietly asked, and by some of their own members, too, to abdicate their position as representative, to acknowledge the ignorance and incapacity of the committee appointed to consider the question of this and other standards, and generally to set themselves up to the ridicule of the photographic world. If the discussion of the matter had been confined to the columns of the photographic journals no notice need have been taken, but the matter is allowed to occupy the whole of an evening of the Society's time. This prompts me to ask whether, considering that papers to be read are supposed to be submitted to the Council for approval, and that the subjects, at any rate, *must* be communicated to *somebody* if they are to be announced on the circular calling the meeting, considering this and also the way in which that

particular paper affected the Society, I wonder whether it would have been "passed" if sent in or announced by any one not a member of Council?

A little matter was mentioned at a past meeting of the London and Provincial Photographic Association which is not so really surprising as at first sight appears. A member stated that he had accidentally exposed the wrong side of a plate, but that it had subsequently "come out tolerably well;" I presume the meaning is that it proved to be tolerably sharp. It very often happens that such treatment would actually *improve* a negative, for there is a strong tendency to ignore the foreground in focussing; the distance or middle distance is made perfectly sharp, and the poor foreground left to itself. Now the effect of reversing the plate in the slide would be to remove the plane of greatest sharpness from the distance to the foreground, where it ought to be if the foreground is carefully and artistically selected; and though the distance may not be so sharp as it was made on the ground-glass, it is quite as sharp as it appears to the eye, while the general "crisping" of the foreground objects, which the eye *does* see sharply, altogether improves the picture.

Of course if the foreground is already in sharp focus such will not be the case, but the picture will probably be ruined unless a small stop is used. Still, the difference that the thickness of a glass plate makes in the definition of the image is far less than would be supposed. I have a negative taken under similar circumstances to those referred to, comprising a wide range of view—water, foliage, and distant hills, with a figure perhaps thirty feet from the camera. The distant objects exhibit no apparent want of definition, while the figure will bear enlarging, and this was taken with a lens of only six inches focus.

On the same page of the JOURNAL there appear the reports of the Derby and of the Leicester and Leicestershire Societies, at each of which papers were mentioned on the same subject. But a very comical lesson is read by a comparison of the titles chosen by the respective authors. Mr. Merry tells *How to Reduce in the Camera by Solar Light from Large Negatives for Transparencies for the Lantern*; Mr. Tucker was announced to speak on *Lantern Slides by Reduction*. If brevity be "the soul of wit," Mr. Tucker possesses that soul, but otherwise Mr. Merry must "take the cake."

Some time ago I spoke about the carelessness that exists on the part of those supplying the reports of Societies. A very flagrant case crops up in the report of a meeting of the Birmingham Photographic Society, where Mr. E. H. Jaques, in the course of his paper on *Instantaneous Pictures and Appliances*, gives a formula for accelerating development in which *drachms* and *grammes* are delightfully mixed up together, and a very important item in the composition of the solution (the water) is omitted altogether. As the formula stands, one drachm, or sixty grains, of bromide of ammonium, and ten grammes, or one hundred and fifty-four grains, of hyposulphite of soda—together, two hundred and fourteen grains of solid matter—are to be dissolved in *one drachm* of ammonia.

The word "grammes" may be, and probably is, a slip for grains, but that being so, the reader is left in doubt as to whether any water is to be used in the formula or the ammoniacal solution of bromide and hypo is to be used "neat." The only object there can be in publishing a formula is that it may be of use to the greatest number possible, and I hold that in order to secure that end it is the bounden duty of individuals reading papers, as well as of secretaries or others supplying reports, to see that the "copy" sent to the press leaves their hands in a complete and accurate condition.

Who will say that albumen prints must necessarily fade after reading that the President of the North Staffordshire Amateur Photographic Association, Mr. C. Alfieri, himself one of the veterans of photography, exhibited a silver print by Francis Bedford, thirty years old, which was stated to be "almost" as good as when first printed? The "almost," I imagine, covers deterioration from dirt and wear rather than from fading; at any rate, if a print will remain even "almost" as good as new at thirty years of age, there is good hope of a longer existence.

That was smart work of Mr. Paul Lange's, if performed with a single camera, as reported at the Birkenhead Photographic Association, even though the necessity for changing the dark slides was obviated by the use of a roller slide. Twelve exposures during the brief five

minutes occupied in the boat drill on board a Cunard Atlantic mail steamer must have kept the operator "moving."

Mr. A. Brothers must surely be a humorist "of the deepest dye," or else the reporter of the Manchester Photographic Society has been making him joke at his own expense. He is stated to have said that during the whole course of his professional career he had always been most willing to impart all the knowledge he possessed to members of this Society *except his secret processes*. Mr. Brothers has done much in and for photography, but a reversal of the proceeding would have been something better worth boasting of. Had the worthy gentleman freely imparted to the Society all his "secret processes" and refrained from wasting their time by talking of what everybody already knew, he would have registered a claim to originality that no one would have denied, not even

MONITOR.

PHOTOGRAPHY ON COLOURS.

It is now several years since any article from my pen appeared in any of the photographic journals of this or any other country. I have, however, in this interval, done a considerable amount of work of more or less interest to photographers, and I propose accordingly for a time to take my old place as a contributor to THE BRITISH JOURNAL OF PHOTOGRAPHY, and unburden myself of what I think may interest its readers. This is a resolution I had formed before seeing the issue of the 10th of June. On the substance of an editorial article in that number, *The Latest Thing in Photography in "Natural Colours,"* I propose to offer some observations now, and proceed next week to commence a short series of articles on a "new principle in physical instruments of quantitative measurement" applicable to a variety of objects. But to my present purpose. I object to the phrase, "*Photography in colours,*" or "*Photographs in colours,*" as applied to the pictures of the "Cellerier Syndicate, Limited," as they are seemingly photographs on colours, which, accordingly, they should be called. It is mentioned in the article I have alluded to, that "the first (or among the first) to apply a coloured paper backing to gelatine transparencies, which in those days were made by the Woodbury process, was R. H. Ashton, who, in March, 1866—now over twenty-one years ago—obtained a patent" for a process of the kind. I happened to be associated with Mr. Woodbury and Mr. Ashton at the time. This was not, however, by any means the first instance of photography on colours. I remember well both Mr. Woodbury and I were amazed at Mr. Ashton's obtaining a patent for "his" process, and we required it explaining to us before either of us could see wherein the validity of the patent lay. The validity of the patent, if it were valid, lay in the circumstance that Woodburytype pictures are not photographs at all, but press copies in a semi-transparent ink from pictures in relief obtained more or less directly by the agency of photography. I have not seen a copy of the specification of the Cellerier process (I presume that it is patented), but the probability is that the novelty consists in the use of developed gelatine transparencies in combination with a coloured backing. If so, the patent (if any) will probably be valid unless it can be shown that the "colouring behind dodge" has been publicly applied to developed gelatine transparencies before, and on this point I am uninformed.

The patent laws, though much amended lately, are much in want of further amendment still. The "colouring behind dodge," which I myself practised four-and-twenty years ago, is a capital idea whoever invented it, but having become public property so long ago as that, it is absurd that Mr. Ashton, or anybody else, should be able to repent it merely on the strength of using a gelatine transparency, which is not actually a photograph, although beyond all doubt a photograph to all intents and purposes; and it is still more absurd that after this process, too, has become public property, a valid patent should be obtainable for the superposition of an actual photograph on a coloured background merely because that actual photograph is printed by the latest of processes—development on gelatine. Yet I fear this will be found to be the case.

D. WINSTANLEY.

E. EDWARDS'S PHOTO-MECHANICAL WORKS, BROOKLYN, NEW YORK.

At the date of writing it is about a week after the time when I had the pleasure of paying a visit to the above-mentioned works, which

are, I believe, the largest, the oldest, and the most important of the kind in America. If the interest taken by English readers in the subject of photo-mechanical printing is at all equal to my own, they will not be sorry to read a short description of Edwards's works.

The processes worked are collotype, photo-lithography in line, and photogravure. Edwards does not produce type blocks, as he is determined to keep the printing of whatever he produces in his own hands—a thing, of course, impossible where type blocks are concerned, as the great use of them lies in the fact that they may be put up alongside of type. I take the collotype process first—or, as Mr. Edwards prefers to call it, "the gelatine printing process," certainly as good a name as collotype, unless, perhaps, it leads to confusion with other processes, such as the ordinary carbon process and the Woodburytype. By the way, Woodburytype, so far as I could gather, is not worked at all in America, and has never been worked with any great degree of success. In the works at Brooklyn the old process in which the bichromated gelatine is supported on copper plates is used. The effect of the copper is to cause a close adhesion of the film to the support, an effect brought about when glass is used by giving a certain exposure through the glass. Mr. Edwards prefers copper because it is not so breakable as glass, and because he considers the exposure of the film through the latter to be a factor of uncertainty. The copper plates are coated with a plain solution of gelatine and bichromate by hand, and are rapidly dried in an oven. They are then exposed under the negative, a few minutes to bright sunshine being sufficient, the exposure being regulated by the aid of an actinometer. The plate is now washed in water till all trace of bichromate has been washed out of it, and is dried, when it is ready for the press. This sounds very simple, and the operations look very simple, but great experience is, in reality, necessary to get results with certainty.

As regards printing, there are the usual hand presses, and, besides these, two power machines, which appear to work admirably. It is possible, by pushing greatly, to get 5000 impressions a-day from each machine, each impression being from four plates, so that actually 20,000 pictures a-day can be got from each machine, or 40,000 from the two might be turned out. I understand, however, that the ordinary turn-out is about a quarter of this. The plates are etched with a simple mixture of glycerine and water, after which a number of prints may be made without re-damping the surface. It is not unusual to pull 5000 copies from one plate, a number which appears enormous. Edwards, however, explained that plates last much better under the power machine than under the hand press, a thing to hear which certainly astonished me greatly.

The work done is of the most varied nature, everything that can be done by collotype being done there. Enormous quantities of the little photographs of theatrical and other beauties which are given away on packets of cigarettes were notable, as also the large productions of the same nature used as window advertisements, &c. The orders for the small ones are sometimes for several millions at a time. That such miniature pictures can be produced closely resembling silver prints shows how fine a texture of image it is possible to get in collotype. These pictures are printed in a number from one plate. Book illustrations of every kind, too, were being produced, and of large work imitation silver prints for advertising purposes—good as examples of collotype, but not in my opinion admirable from any other point of view. The thing most notable and interesting to me, however, was a series of reproductions of recent photographs by Muybridge. All readers will remember well his photographs of the horse in motion, &c. These, wonderful as they were, were defective, inasmuch as they showed no modelling—were, in fact, mere silhouettes. They were taken on wet plates; although when they were first published, at just about the time when gelatine dry plates were becoming popular, there was a general misconception that they came as one of the early examples of the wonders that could be wrought by the aid of the new dry plates.

In the new series the modelling is as good as could be desired, and the subjects are particularly interesting. There are animals of various kinds—a series showing most accurately a complete cycle of the flying of a bird, for example—but the majority of the subjects are human. They show almost every kind of motion conceivable. Walking, running, jumping, ascending and descending stairs, turning somersaults, bowling, batting, throwing and putting weights, &c. &c. The figures are male and female, nude and clothed. Wherever possible, two series have been taken to show the same cycle of motions, one nude, the other clothed, so that the positions taken by the clothing may be accurately observed. As, however, a number of the photographs represent different phases of dressing and undressing, this cannot be carried out in all cases. Some of the photographs—especially those of children—are, as pictures, quite beautiful. I do not know whether these new efforts of Muybridge's genius have yet reached

England, but it is to be hoped they soon will, as I can conceive of few things likely to be more useful to artists and others.

Of the photo-lithographic work I think nothing particular is to be said, as it is, so far as I know, worked as it is all the world over. The negatives are made on wet plates, and seemed to me much thinner than I should have thought necessary. The image is printed on a piece of sensitised transfer paper, which is then inked up all over. The ink is then washed off, so far as possible, adhering, of course, only to the lines where the gelatine, &c., has been rendered insoluble by the action of light. The ink is then transferred to the stone, and the various processes of gumming, rolling up, etching, printing, &c., are conducted in the usual manner, power machines being, for the most part, used.

The photogravure plates are produced by the Klic process—that is to say, a plate of copper is covered with bitumen in the form of fine powder, so as to produce a grain. The plate is then coated with a sensitised gelatine film, which is exposed under a transparent positive, and afterwards the plate is etched with any fluid which will attack copper, but not gelatine. The result is that the etching goes on less where the gelatine has been rendered insoluble by light than where it has not, a grained intaglio plate being the final result.

Edwards did not show me the actual powdering and etching of the plate, but he told me that the powdering was performed by throwing up a certain quantity of finely powdered bitumen, and catching a certain quantity of it on the plate as it fell. The plates as they came from the etching I saw; they were held intaglios requiring scarcely any hand work. The hand work, indeed, was, so far as I could tell, by comparing untouched and touched plates, confined to working a little in the very deepest shadows, and burnishing up small touches of high light so as to give sparkle. The plates were printed from at a greater rate than I thought possible, probably because of the boldness of the etching. A plate is inked all over, the greater part of the ink is removed by a cloth, and then the flat of the hand, first covered with a little powdered chalk, is quickly passed over the face of the plate, removing the last trace of ink from the highest light, and becoming apparently without what I may call discriminating rubbing, just the desirable quantity of ink on each spot of the plate. I mean that there appeared to be no necessity to pick ink out of special parts of the plates, or to “dodge” in the inking. The plate is then pressed under an ordinary copper-plate printing press, and the proof came out finished.

A word as to the results. Mr. Edwards does not work the very large sizes that one sees coming from the Continent; but up to a fairly large size produces certainly as fine photogravure work as I have seen anywhere. I have spoken of the etching being bold, but it must not be supposed that the results are other than delicate. They are, indeed, delicate in the extreme. The arrangement of subject, &c., is also generally very artistic. The Meissenbach method of obtaining a grain is used for the photogravure as well as the Klic, but the results are, in my opinion, at any rate, much inferior. A very beautiful result is got by printing from the copper plates on Japanese paper. The texture of this is delicate in the extreme, and this paper is particularly well suited to receive the image. These prints on Japanese paper are mounted with spots of paste at the four corners on a white mount, with a curious and very interesting result. If the mount be held quite flat, so that the Japanese paper is scarcely in contact with it, the image appears very soft and delicate. By bending the mount but a very little backwards the paper is brought into close contact with it, and the image instantly stands out bold and clear.

I must not omit, whilst speaking of Edwards's works, to mention a series of photographs which particularly took my attention. They were a series of theatrical groups done by artificial light on the stage. We have had a good many attempts to produce such pictures in England, and the results have certainly been “interesting,” but when that is said, about all that can be said of them has been said. When I saw the groups I refer to, showing the actual action in Shakespearean plays, I remarked, “Ah! but these are from paintings.” It is a sad comment on, at any rate, some branches of photography, that whenever we see a particularly good result we incline to think it is from a painting. But so it is. It was long, in this particular case, before I could persuade myself that the groups in question were not from paintings, so perfect were the posing, the apparent action, the grouping, the lighting, and the general arrangement, the scenic background actually giving the idea of distance. I was told that the exposures were only two to three seconds, the lighting being by I am afraid to say how many are electric lights—I think a hundred. Mr. Edwards expresses his intention of attempting, if he has more work of the kind to do, to get what he wants with drop-shutter exposures.

Mr. Edwards gave me the following interesting statistics as to the number of impressions that can be pulled from plates, the rate, &c.:—“The number of prints that can be taken from one gelatine plate on the hand press varies widely with the printer, the negative, the subject, the paper, and the weather. With a good printer, a favourable subject, in cool weather, 2000 and 3000 copies are not unusual. On the other hand, some plates will only last for 50 copies. The average number does not exceed 250 copies. By machine printing the same conditions hold, but the number of copies is larger; 10,000 from a plate have been printed, but the average number is from 800 to 1000. The average number of impressions a hand-press printer will make per day, taken small and large, does not exceed 150; by the machine, does not exceed 1000. The number of photogravures (here we come into the region of certainties, more nearly) that can be pulled from one plate without re-steeling is 3000; with re-steeling, from 8000 to 10,000. The average number of impressions pulled per day, say, of a subject about 9×7 on paper 11×14 , is 200 to 300.”

W. K. BURTON.

PHOTOGRAPHY PAST AND PRESENT.

[A Communication to the North London Photographic Society.]

THE Society whose name has been revived in this flourishing association of professional and amateur skill, was the first photographic society to which I ever belonged, and as now I have been so courteously elected an honorary member of it, I feel much pleasure in contributing my mite in the form of a paper, in which I shall endeavour to call your special attention to that phase of photography that is perhaps more talked about than practised, although I think it is perhaps the only one in which we may anticipate continuous improvement.

An opinion I have held for many years past, and see no reason to change, is that the artistic side of photography will eventually dominate every other. Manipulatory excellence has a limit, but artistic excellence has none. We should therefore spare no pains in the improvement of this important quality, and we may rest assured that any care and trouble will amply repay us in much better work. The late South London Photographic Society adopted a plan suggested by myself, with the idea of improving our work in this direction, by instituting a series of artistic competitions, which, somehow or other, did not meet with the energetic support of the members I had hoped to see—may be, the moribund condition of that Society had something to do with it. Perhaps, if a similar plan was revived in this Society, with its redundant energy, the results might be different; anyway, I throw out the hint for what it is worth.

The conditions under which photography now and a quarter of a century ago was worked are so changed they seem to be almost different arts. It is no waste of time if we occasionally devote a little to the discussion of old plans and processes that in their day (scarcely yet passed) have done so much for human progress and contributed so greatly to the happiness and welfare of mankind. There is doubtless hidden in past and discarded methods of working germs that will from time to time blossom forth into useful and valuable ideas, and in some new guise challenge attention, and perhaps bring fame and fortune to those sufficiently far-seeing to appreciate their value. Photography has perhaps afforded more pleasure and effected more good to all classes of society than any other art during the present century, a period abounding in good things and unprecedented in the development of all arts and sciences. At the present time the simplest operation or the most elaborate and scientific investigation receives help and aid from photography, and its usefulness seems ever on the increase. So much has been said and written about it that to say anything new is well nigh impossible, and, whatever it may be, it is little else than a *réchauffé* of old matter gossiped over times and oft.

Photography to its disciples of the present day is mere child's play in comparison with the old wet collodion process. To go out photographing for pleasure then was a serious undertaking, so serious that few save the more adventurous and enthusiastic ever ventured. This was the programme for a day's pleasure in the old days. In the first place a list of requirements had to be gone carefully through—even now this plan has considerable advantages—and the different articles checked off as they were set aside. Now, what were the articles? Firstly came a tent of some kind, with its fittings, bottles, dishes, measures, cups, buckets, and jugs; a long list of chemicals in bottles and parcels, ready-made developer and fixing solutions, plate boxes, draining boxes, racks, brushes, plates and plate holder, collodion, with a great many other odds-and-ends, and last, but most important, that tantalising, worrying provoker of bad language, the nitrate bath. It was almost as customary for a photographer in the old days to ask

his friend how his bath was working as to inquire after his health. The accidents and complaints to which this single important necessary to work was subject was something alarming; it would, after the most fair promises, become afflicted with pinholes, fog, streaks, or markings of innumerable kinds, all objectionable and damaging to the results. You might begin a day's work with everything favourable, then suddenly the bath might go wrong and unworkable just when there was every necessity for things to be working at their best—some especially favourable conditions of light, or some special group difficult to get together. A reserve bath was usually taken, but this added to the weight of the outfit, and time was lost in getting ready this substitution. Making the silver bath right in the first instance was a matter of chemical legerdemain, and keeping it so afterwards a never ending source of anxiety till it was finally boiled down or put to the residues. Then, supposing the bath was right, there was the collodion, which might be too thick or too thin, or not clear, or crapy, or something objectionable. Again, supposing this to be as it should be, the plates had to be coated, perhaps on a windy day in a dusty locality, no easy task without matter getting into the wrong place, causing defects; or the surface of the glass might be defective and show stains and markings on the finished negative. All these difficulties being surmounted, and the plate carefully prepared, exposure right, and development perfect, the film might take to floating off the glass, and ending its career in the drain. Should it escape all these pitfalls, it had to be stored in the draining box, brought home to be dried and finished; these latter stages being rather less troublesome than its modern successor, the gelatine dry plate, save that it was infinitely more tender and liable to injury. When, however, it was successfully finished, the result was simply perfection, and up to date remains a standard for all other negative processes.

It will be readily understood from this slight sketch that outdoor photography was really a serious undertaking, and that much deliberation and thought were required before adopting it as a hobby and recreation. With all its faults, one has a lingering respect for a servant that has done such good duty, and prepared the way by sound and solid instruction for the process which has almost, if not entirely, superseded it. The advantages of a thorough knowledge of wet plate work reduces the manipulations connected with dry plates to a mere bagatelle. The mechanical difficulties, and they were not a few, are almost wholly done away with, unless the photographer makes his own emulsion and coats his own plates, and one inestimable advantage is gained, he is independent of time. With wet collodion it was absolutely necessary to use the plates within a short time of their preparation, for after a few minutes they began to lose sensitiveness. About half to three-quarters of an hour was the time allowed for the longest exposure. Not much was gained by increasing it. The more rapidly they could be used after exciting the better was the result. Many plans were used to preserve their sensitiveness and prevent irregular drying. Wet blotting-paper at the back of the plate, a sheet of glass placed over in front of the film, strips of blotting-paper for the plate to rest on, sponging out the interior of the camera or keeping a piece of damp cloth inside it, the use of deliquescent salts in collodion, glycerine in the silver bath, or a short washing of the sensitised plate in distilled water after exciting with a redip in the bath before development; these and numerous other plans more or less useful were resorted to to beat time. If we add to all this the mess, slop, and stains usually accompanying the preparation of a few negatives, the shyness with which photography was looked upon is easily accounted for and not difficult to understand, and the horror with which the housekeeping authorities viewed amateur photographic experiments is far from obscure. An objectionable process, not always carried on by unobjectionable people, was not altogether the sort of thing to recommend itself as a hobby. Its professors, many of them very estimable men, were looked on with slight favour, photography as a business not being the best recommendation to society. There were some few devotees of the art who courageously strove to raise its social status, but it was uphill work, and it was not until gelatine dry plates became established in public favour that the turning-point was reached, and the hitherto patrons of the photographer became photographers themselves, extending the right hand of good fellowship to those previously looked upon with shyness and misgiving. Since then photography has rapidly advanced in favour, and from being looked upon as a refuge for the destitute and a resort for the needy and disreputable, has become the sport of kings. This, the handmaid of science, is now recognised, appreciated, and beloved by all classes of society, and at the present time no accomplishment is in greater favour than photography. From my experience (and I have no doubt I echo the feelings of many) its pursuit only gives one

a greater liking for it, and has a growing and increasing hold on one's affections if fairly successful results are achieved, and after more than a quarter of a century's practice there is as much pleasure felt in seeing the beautiful, delicate image grow under the developer as ever there was.

Modern photography, especially in the field, is free from nearly all the troubles and annoyances of wet plate work. There is, in fact, no more, perhaps even less, than that attached to water-colour sketching. Under such conditions all the photographer's artistic nature ought to be fully exercised, the art side of photography occupying his entire attention. Making a negative, so far as the necessary field work goes, is no trouble. Anybody can do it, but (and there is a good deal in a "but" sometimes) there is in making a picture. I look on it that as soon as proficiency is gained in the necessary manipulations, and they are but few, the whole thoughts of the photographer should be concentrated on the artistic rendering of anything he may attempt to portray. A plate should never be exposed unless there is a fair probability of a picture resulting in the subject chosen. That very common plan of dubbing a failure a study because it is scarcely worth calling a photograph, and certainly is not a picture, is to be deprecated. Sooner bring home your apparatus unused than that the plates should have been exposed indiscriminately on any building or subject that happened to present itself, for, bear in mind, *one thoroughly good and artistic negative* is of more value and will afford more gratification than any number of indifferent ones. The beauty of a good negative grows under frequent inspection, and the faulty one gets more and more disappointing. (It must be understood I refer especially to the capabilities of the negative for producing a good print—its ultimate use—and not merely to the negative itself.) It is not always the prettiest negative that gives the best prints. However, a thoroughly nice-looking negative does not often disappoint one. Let any amateur ask himself what is his percentage of medium and indifferent negatives out of a day's work, and how many artistic and fine compositions, such that some possible and easily-made alteration at the time they were taken would not improve, could be chosen out of a year's work. I am afraid the result would be unsatisfactory.

The low percentage of good work is in some degree due to the anxiety to fire off plate after plate at anything without considering if the object is worth the plate. If all who take up photography as an amusement tried to make *pictures* instead of only sharp negatives, we should soon see an improvement in the work. It certainly requires education of the faculty of seeing even to see a picture. Many will go through a most picturesque neighbourhood and never see anything at all, whilst others will in a far worse locality see a picture at every turn. This training of the eyesight may in a great degree be self accomplished by the careful study of the works of artists of repute, and at the same time making a mental analysis of them by endeavouring to ascertain the why and the wherefore of the position of the various objects, the arrangement of the light and shade; for in all good pictures there is nothing put without a purpose, and nothing can be taken away without in some degree damaging the results. Again, every square inch in some pictures is a picture in itself, so well has the composition been thought out and harmonised in one glorious whole. It may be said that photographers are the creatures of circumstances, and cannot use such discretion in composition as the painter. This is true in a degree, but they have compensating advantages in their command of rendering detail and the power of accurately registering evanescent effects, which are far in advance of any possible hand work. There are undoubtedly subjects that photography fails adequately to represent, also an unlimited number that can be properly rendered, and where painting and photography are on more of an equality as truthful recorders of nature.

One kind of subject we have all been educated to falsely appreciate, and that is the magnification and undue prominence of distant objects. Artistic license says it gives a better and more artistic effect to magnify the distance than to represent it accurately. Is this really so, or is it a matter of persistent error that familiarity has made us regard as truth? There is no doubt that we generally look upon mountains and distant objects in photography as dwarfed simply because we have been used to see them painted on a scale perhaps more than twice as large as they ought to be. Unless the lenses we use are of exceptionally long focus, distant objects do not come up to our expectations as to size, and even then there is an impression that they do not look as important as they ought. This effect is possibly owing to the aerial perspective in the negative being exaggerated and the distances printing much lighter a tint than they should, and becoming technically known as *buried*; but, whatever the cause, photography at the present time fails to give entire satisfaction on

this particular point. We have, however, plenty of subjects that do give entire satisfaction, and the photographer shows his skill in selecting the most suitable. Here, then, we see the vast superiority of modern dry plates over wet collodion. Thousands of subjects were closed books to the wet plate man that offer most tempting and novel effects quite within the range of the gelatino-bromide film. In going for an outing, he starts without the worry of having to take a laboratory with him and that awful bath, but, provided with a kit that can be put in his pocket or flung over his shoulder, is prepared for all emergencies and is independent of extra aid, his motive power is self-contained, to be exercised at discretion. This independence is in itself a wonderful aid to picture making, and in the wet plate days several attempts were made to provide apparatus that would permit it, for instance, Dubroni's and Edwards's graphogene, neither of which were pleasant to work with, although by chance you might get a tolerable result with either.

The modern photographer has much to be thankful for, and only he knows how much who has struggled with processes in the early days. I sometimes marvel how such good work could be done under such conditions, and a shudder passes through one to think of having to return to the old plans. However, to bring this prosy paper to a close, I would impress on all who indulge in the pleasures of photography that they should pay special attention to the artistic rendering of everything upon which they bring their cameras to bear. No matter how simple and unpretending, it will, if invested with real artistic qualities, be bound to please, when the most ambitious flight without this quality will be unsatisfactory and disappointing.

EDWARD DUNMORE.

THE DERBY EXHIBITION.

THE Summer Exhibition of Photographs at the Derby Corporation Art Gallery was opened on Monday last.

On the previous Saturday the judges, Mr. W. England, Vice-President of the Photographic Society of Great Britain, and Mr. H. J. Whitlock, of Birmingham, having examined the exhibits, made their awards as follows:—

For the Best Photograph in any Class.—Gold Medal—J. Lafayette, Dublin.

PROFESSIONAL WORK.—1. *For Landscape or Seascape, or series of.*—Silver Medal—G. West & Son, Southsea. Bronze Medal—H. Symonds, Portsmouth. Certificate—T. A. Green, Grasmere. 2. *For Portrait, or series of.*—Silver Medal—W. J. Byrne, Richmond. Bronze Medal—McLiesh, Darlington. Certificate—W. W. Winter, Derby. 3. *For Architecture, Interior and Exterior, or series of.*—Silver Medal—Richard Keene, Derby. Bronze Medal—Not awarded. Certificate—J. W. Price, Derby. 4. *For Genre or Figure Pictures.*—Silver Medal—F. Whaley, Lincoln. Bronze Medal—Syd. Sawyer, Newcastle-on-Tyne. Certificate—R. H. Lord, Market-street, Cambridge.

AMATEUR WORK.—1. *For Landscape or Seascape, or series of.*—Silver Medal (given by the *Amateur Photographer*)—Frank Cooper, Derby. Bronze Medals—J. W. Robinson, Gateshead, and H. B. Berkeley, London. Certificate—Herbert Strutt, Makeney, Derby. 2. *For Portrait, or series of.*—Silver Medal—Not awarded. Bronze Medal—Edwin W. Alabone, London. Certificate—E. W. Alabone, London. 3. *For Architecture, Interior and Exterior, or series of.*—Silver Medal—Not awarded. Bronze Medal—Not awarded. Certificate—James C. Grinling, Barton-under-Needwood. 4. *For Genre or Figure Pictures, or series of.*—Silver Medal—James Crichton, Edinburgh. Bronze Medal—John F. Roberts, Camera Club, London. Certificates—Edwin W. Alabone, London, and W. Clement Williams, Halifax.

Special Certificate for Excellence of Work.—Nine Photo-micrographs by W. H. Pratt and T. W. Cave, Nottingham.

Mr. Keene's Medal to Member of Derby Photographic Society.—W. W. Winter, Derby.

The collection by local photographers is varied, and is generally of excellent quality. W. Winter shows a number of excellent children's and other portraits, and a *genre* picture, *The Rynester and his Victim*.

R. Keene exhibits a variety of those interior views in platinotype for which he has acquired a well-deserved reputation, together with a series of fine views of Osmaston Manor; while W. Davies contributes views of the charming scenery of Derbyshire; T. Seotton a picture, *Shoeing*, direct from life, the *Entrance to Miller's Dale* and other landscapes taken in the Lake district and elsewhere, together with his large and excellent group of the members of the first Photographic Convention.

E. J. Lovejoy has views of Yarmouth Quay and fishing-boats in that vicinity, with others. J. W. Price shows several snow and frost scenes and a fernery.

The foregoing are local professionals; the amateurs of the Midland town who exhibit include H. Andree, who contributes *Norfolk Broads, Brook Scenes*, in platinotype; Frank Cooper, who shows a view of Old Derby, and others, but whose views at Weston-on-Trent are worthy of special notice. W. G. Haslam has photographs of machinery and other views; H. E. Merry, twelve Derbyshire views; C. L. Schwind, six views of Ferriby Brook, a study of hoar-frost, and other scenes; and C. E. T. Terry, who, in addition to landscapes, also exhibits portraits. These comprise the Derby contingent of the exhibitors. But we must omit mention of others till next week.

The success of the Exhibition is not a little owing to the efforts made by Mr. W. Crowther, the Curator.

PHOTOGRAPHIC PAPERS AND PAPER MAKERS.

II.

THE ordinary papers in the market for commercial purposes may be divided into two great classes, namely, those which are resin sized and are largely used for book and newspaper printing, and those which are sized with gelatine, which is the case with most of the English writing papers. To the latter class of papers attention will now be given.

Perhaps the clearest way of dealing with the subject will be to give the formulæ by which recognised photographic paper is sometimes sized, and afterwards to compare such paper with that sized for writing purposes in the ordinary manner at English mills. Captain Pizzighelli and Baron A. Hubl have published that their plain paper for the platinotype process is free from the ultramarine sometimes used to give blueness to paper, and which turns yellow in any process in which it comes into contact with free hydrochloric acid. The paper they use has a felt-like surface showing no grain, and it is made for them by Messrs. Gustav Röder & Co., of 10, Wallfischgasse, Vienna; it bears the name of "ivory vellum paper" and may be obtained either hot pressed or unglazed. At the mills it is half sized with resin size, so has at the outset a partial power of resisting the absorption of aqueous liquids. Writing papers which have to be finally sized with gelatine are commonly half resin sized in the first instance. On receipt of the paper from the mills they put the final size upon it themselves, by first allowing ten grammes of gelatine to swell for half an hour in 800 c.c. of water; the surplus water is then poured off and heated to about 60°C., after which it is added to the soaked gelatine; when the latter is dissolved, three grammes of alum and 200 c.c. of alcohol are added. Such a solution, they say, does not set if kept in a warm room, heated to not less than 18°C. They then filter it through clean canvas into a tray, and dip the sheets gradually one by one into the solution, then carefully remove air bubbles by means of a hair brush, and afterwards allow each sheet to remain well immersed for two or three minutes in the liquid; it is then drawn out with a rapid and continuous motion, and by means of clips is hung up to dry in a place warm enough to allow the surplus gelatine to drip off, and not to collect in a ridge at the lower end of the sheet. This coating may be accomplished rapidly, and if the drying is quick in winter near a stove, or in summer exposed to an Austrian sun, the second coating of gelatine, which is always given, may be applied in about twenty minutes after the first. In the drying which follows, that edge which was previously lowermost is now clipped so that it shall be at the top, so that the finished sheet may be the more evenly coated over its entire surface. The strength of the sizing solution is sometimes varied to suit the different powers of absorption occasionally exhibited by various samples of paper.

At the outset I may state that I have sized various samples of good English vellum wove papers in the manner above stated, and for iron and platinum processes have so far found them to work without spot or blemish, and on first dipping them into the sizing bath I found out the cause of one class of photographic failures which has sometimes been erroneously ascribed to chemical impurities. In the bath, blotches appeared due to unequal absorption of the liquid, and I saw that those blotches were of the same general shape as faults in prints which Mr. Barker once publicly exhibited as due to impurities in English made papers. Long immersion in the sizing bath did not cause the blotches to disappear; there were evidently portions of the paper which the colloidal solution would not fully penetrate. When the same sheets were subsequently used for photographic purposes, the same irregular spots of unequal absorption of liquids became visible in every bath in which they were immersed; they were invisible in the paper when dry, and invisible in the finished photographs, which had evidently been saved from destruction by the gelatinous substratum which had been applied. This raises the question whether with good and careful sizing many an ordinary paper

may not do for photographic purposes, and whether the absolute purity and evenness of the paper itself are of quite the importance usually imagined.

Possibly my success in this matter was due to my care in using only the best and purest materials, a plan which should always be adopted in experiments intended to clear up scientific points. The gelatine used was not of ordinary character, but the hardest to be obtained, namely, "Coignet's Gold Label Gelatine," which sets at such a high temperature that, unlike Captain Pizzighelli's bath, it would not keep liquid in a warm room, but its temperature had to be constantly kept up by a hot water bath. Hence the word "gelatine" as used by Pizzighelli and Hubl is somewhat too indefinite for practical purposes.

As to the differences in gelatine, the influence of which in sizing papers must evidently be experimentally ascertained, Dr. Eder says that one test of the quality of a gelatine is the amount of ash it yields when incinerated; this varies from one-half per cent. in good samples to five per cent. in those which are inferior, and to ten per cent. if adulterated with alum. Captain Abney, in his *Photography with Emulsions* (London: Piper & Carter, 1882), says that good gelatine should absorb from five to ten times its weight of water, and he gives the following table:—

Name of Gelatine.	Ash, per cent.	Water absorbed by 50 grains.
Coignet's gold label	1	nearly 7 drachms.
" special	1	" .. 7 "
Nelson's No. 1 photographic	2	" .. 5½ "
" opaque	2	" .. 8 "
" amber	1	" .. 4 "
Ordinary French (not branded) 2	"	" .. 6 "
Swinburne's No. 2 patent isin- glass	1	" .. 5½ "
Cox's gelatine in packets	1	" .. 4½ "
Russian isinglass	1	" .. 2½ "
Gelatine supplied through Mr. Henderson	2	" .. 8 "
The Swiss gelatine supplied through Houghton	2	" .. 5 "

As regards the influence of temperature upon the solubility of various brands, Abney says that Nelson's No. 1 gelatine, in warm weather, will dissolve at the temperature of the room in which it is soaked; the other extreme is Coignet's gold label, which will not melt under a temperature of about 110° Fahr. In their setting powers these two gelatines are the most opposite, for at a temperature of about 75° Fahr. Nelson's will scarcely set at all, whereas Coignet's will set in a short time.

One decidedly good result I obtained by the use of a gelatine of high melting point was, that there was little or no tendency to drip when the sheets were taken out of the bath; the sizing set at once at the lower temperature of the air, only two or three drops of the solution falling from large sheets.

In my next, Pizzighelli and Hubl's formulae will be further criticised, and problems connected with the manufacture of the papers themselves will be considered.

W. H. HARRISON.

EDINBURGH PHOTOGRAPHIC SOCIETY.

A DEMONSTRATION of stripping films was given before the Edinburgh Photographic Society at their last meeting by Mr. J. M. Turnbull, who explained the working of stripping film negatives, and, in the course of his remarks, gave a demonstration of the removal of both collodion and gelatine films from their paper and glass supports. He said the paper negative was a revival of a very old idea in connection with photography, and the latest form of argentic picture making was in reality, to a great extent, a return to a good old style, the details of which, he said, are, nowadays, only to be found in the records of our history of our art, or in the memories of a comparatively few of our veteran associates. Talbot, whose name for many years distinguished a process, was an eminent pioneer in this field of photography. Our townsman, D. O. Hill, produced pictures of this class, and his negatives were not much behind what we have now. Some of his work, both negative and positive, is to be found in the Society's album, and is characterised by breadth and artistic feeling.

Leon Warnerke brought out his transfer collodion films about twelve years ago, and a good display of them was made at the Society's Exhibition in 1876. His process was to build up on paper a film composed of alternate coatings of rubber and collodion, which, after development—the picture itself being on collodio-bromide emulsion—

was laid down on glass. Subsequently it was damped on the back with benzine, and stripped. He extensively advertised these films at one-third of a penny per square inch. A feature in connection with them was their employment in the making of combination negatives when sky and other effects were desired, sometimes two, and even three, negatives being printed together. In this way also a style of portrait was introduced, the bust being printed as if in an oval frame. These films were slow compared with what we are accustomed to now.

Morgan & Kidd were the first to introduce commercially paper coated with gelatine emulsion, since which time great advances have been made in preparation and practice in relation to it. When the negative is left unstripped from the paper, a certain disadvantage arises, from a degree of grain showing in the finished print, especially in soft sky portions, and when delicate half tones largely predominate. The printing also is slower than with glass negatives owing to this nature of the support. These, and other drawbacks, no doubt suggested and hastened the adoption of the stripping film, which is only new in the sense of its composition and treatment. I may say that I stripped a number of large negatives for our late President, Mr. Lessels, a few years ago, which were intended for collotype printing. I coated the plates first with a thin solution of rubber, before the emulsion was put on. The negatives, on thin plates, were then first coated with collodion, followed with a stripping varnish. They came off quite successfully and easily, and the plate I now strip before you has been treated in the manner I have described. I draw a sharp knife all round the picture about a quarter of an inch from the edge, and by lifting a corner it comes off without any trouble, as you see.

Strippers, as they have been termed, have only been in the market for a few weeks as yet. They are composed of a thin film of soluble gelatine on the paper support, over which the harder emulsion is laid, and which will stand considerable heat without dissolving. When it is decided to strip a negative, I proceed in this way, which I think to be a decided improvement upon that given by the Eastman Company, because it is more simple and more expeditious, and at the same time giving equally perfect results. I found on experiment that there was no need to let the negative dry before stripping. After exposure and development, lay the picture down on glass which has been previously coated with either thin rubber or collodion—I prefer collodion. This should be done in a flat dish of water. When both are in contact, lift out and squeegee down. After two or three minutes, put the plate into hot water, and the paper will begin at once to show signs of coming off. Pull it gently away with the fingers, and you will find the negative now left upon the collodionised glass. A soluble gelatine will be found upon it which is easily removed. Now, while the plate is still wet, lay down the skin upon it which is to act as the final support of the negative; or, what comes to the same thing, coat it with stripping varnish, and set up to dry. I found the formula given with the films took a very long time to accomplish this—some six hours, and often more—and the cause seemed to me to be an excess of glycerine; I therefore have altered it considerably. I take—

Coignet's gelatine	8 ounces.
Glycerine	½ ounce.
Carbolic acid	1 "
Water	30 ounces.
Methylated spirit	20 "

The gelatine is soaked in the thirty ounces of water, and, when soft, melted, the other ingredients being then added. This varnish will be found to dry rapidly, and renders the use of "skins" unnecessary.

Mr. Turnbull exhibited a negative prepared in this way, and stripped it by the aid of a knife as in the former case. He remarked that development and stripping, when a few negatives are in question, may go on continuously till all are finished, the one becoming ready as the other is stripped. The lightness and portability of these films, either for carrying in the field or transport otherwise, were remarked upon, and the advantages they offered in cases where reversed pictures were required. Mr. Turnbull also alluded to a handy means of levelling plates while coating, which he had published in the journals about 1874. It was to make use of Nettlefold's screws for picture frames by fixing them in a board at points forming a triangle, raising or lowering them as required till a perfect level is obtained. The plate being warmed, coating is then made easy and regular.

The roller slide, and the various improvements effected upon its introduction about thirty years ago, was briefly gone into, Eastman, Lejeune & Perken, Morgan & Kidd, Warnerke, and McKellen's apparatus being severally referred to, as also the tissues of Woodbury, Vergara, Pumphrey, &c.

A vote of thanks was accorded to Mr. Turnbull for his interesting and timely demonstration and remarks.

PERCENTAGE SOLUTIONS—WEIGHTS AND MEASURES.

As a supplement to your article in last week's JOURNAL, on *Percentage Solutions and Weights and Measures*, I have drawn up the enclosed comparative table of English weights and measures, which will, I think, be found interesting and useful, as showing at a glance the relations, as well as the inconsistencies, of our barbarous system. The two columns headed "Parts"—one taking the minim the other the grain as the unit part—will enable any one to translate into parts of either kind any of the units of measure or weight otherwise incommensurable. These columns also show the ratios between the various units. Thus the pound avoirdupois is to the pound troy as 7680 is to 6319.543, or as 7000 to 5760; while the proportions of the three units bearing the name of drachm are as 65.829, 60, and 30. It will be seen that avoirdupois weight and fluid measure are closely connected. To make them identical in form would need merely the change of one of the drachms (which are as 2 to 1), the adoption of the American pint of 16 fluid ounces, and the use of a minim weight in place of the grain. The relations between measure and weight apply, of course, to pure water at the standard temperature and pressure, and would be affected by the specific gravity of any other fluid or solution.

COMPARATIVE TABLE OF MEASURES AND WEIGHTS OF WATER.

1 minim of water weighs .9114583 grain.

1 grain " measures 1.09714285 minims.

Parts (minims).	Fluid Measure.	Avoirdupois Weight.	Apt'h'eries Weight.	Troy Weight.	Parts (grains).
76800	Gallon	10 Pounds			70000
9600	8	10			8750
7680	Pint	Pound			7000

H. G. MOBERLY.

ON MR. DALLMEYER'S PROPOSED ALTERATION OF THE STANDARDS FOR LENSES OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

[A Communication to the Photographic Society of Great Britain.]

It must not be expected that I have anything new to bring before the meeting to-night, as the subject of my paper has been pretty vigorously discussed during the last month in the *Photographic News*. I think, however, that it is of sufficient importance to receive the serious consideration of this Society. The name of Dallmeyer will command attention to any suggestion concerning that important part of photographic apparatus, the lens, and I need scarcely, therefore, say that we ought to give every attention to anything coming from one of such large experience as Mr. Dallmeyer. I had the honour to be one of the Committee appointed by the Council of this Society to consider and report upon the best means of attaining uniformity in the construction of apertures, in the diaphragms of lenses, flanges, and camera screws. I naturally, therefore, feel great interest in anything bearing on this matter.

The credit of getting a Committee together to arrange standards for photographic lenses is, I believe, due to the efforts of Mr. Warnerke. If

my memory serves me rightly, he originally proposed $\frac{f}{2}$ as the unit for our standard apertures; but we found that numbers representing the relative exposures for small apertures became inconveniently high, and, in consequence, $\frac{f}{4}$ was chosen. Moreover, if I remember rightly, the impression was general that $\frac{f}{4}$ represented the approximate full aperture of the ordinary Petzval portrait lens. At any rate, I myself was under that impression; and lenses of this description being in very general use, we thought $\frac{f}{4}$ would be a very good unit to start from. No doubt it is so, but the question now arises, Can we have a better

unit? We are told by a very high authority that we can, and therefore, without prejudice, with a desire for progress, and with that element of conservatism to preserve that which is good, we ought to logically consider the question.

Mr. Dallmeyer wishes us to change our standard from $\frac{f}{4}$ to $\frac{f}{\sqrt{10}}$. To those few who do not quite grasp the difference, I might say that, supposing the present standard aperture required sixteen seconds' exposure, Mr. Dallmeyer's standard would require ten seconds, and would be thus a considerably quicker lens.

Mr. Dallmeyer's reason for the suggested alteration is that the standard numbers would then become a factor of the squares of the denominators of the fraction expressing intensity—in fact, identical, except in the position of the decimal point. Moreover, the system would be a decimal one. There may be a few who would like this more clearly explained. I will, therefore, at the risk of being tedious and rather simple, try to explain what is meant as clearly as possible.

The present standard aperture is $\frac{f}{4}$. Mr. Dallmeyer's proposed standard is $\frac{f}{\sqrt{10}}$, or $\frac{f}{3.162}$ &c.

Now, of course, when we want to compare the relative exposures of various apertures, we know that they are proportional to the squares of the denominators of the fractions representing the respective intensities.

For example, to compare $\frac{f}{4}$, the Photographic Society's standard, with $\frac{f}{8}$, the full aperture of the rapid rectilinear, we square the denominators, which become respectively 16 and 64. Now, if we let the 16 represent unity, we must divide the 64 by the 16, to express the relative exposure of the $\frac{f}{8}$ in the terms of that unit; 64 becomes our divisor, and, as it goes 4 times, we say that $\frac{f}{8}$ requires 4 times the exposure of $\frac{f}{4}$; $\frac{f}{8}$ is, therefore, No. 4 in terms of the standard.

Now, with Mr. Dallmeyer's standard, as soon as we want to express any fraction of intensity in terms of his standard, 10 becomes our divisor, because we start with $\frac{f}{\sqrt{10}}$. To square the $\sqrt{10}$ simply means 10, and 10 is, of course, a much more simple divisor than 16. Comparing $\frac{f}{8}$ with $\frac{f}{\sqrt{10}}$, we square the 8 as before, and then divide the result 64 by 10, which almost every one knows simply means putting a decimal point in, and we get 6.4 as representing $\frac{f}{8}$ in terms of Mr. Dallmeyer's standard.

Inversely, if we want to know the fraction of intensity represented by apertures already expressed in terms of the unit, we must multiply such apertures by the unit divisor, and then the square root of this result will give the denominator of such fraction; thus, taking No. 4 P. S. :—

$$\text{Denominator of intensity fraction} = \sqrt{16 \times 4} = 8 \therefore \text{Intensity of fraction} = \frac{f}{8}.$$

Taking Dallmeyer's standard—

$$\text{Denominator} = \sqrt{10 \times 6.4} = 8 \therefore \text{Intensity fraction} = \frac{f}{8}.$$

So far I have taken an intensity fraction favourable to the Photographic Society's standard, as it makes a complete number, and one would say that, for trouble of calculations, there is not much to choose; but when we come to small apertures, I think it will be generally admitted that Mr. Dallmeyer's standard gives less trouble, because as soon as we get the square of the denominator the standard terms are visible at once, without further trouble. For instance, let us take $\frac{f}{26}$ (the fourth stop of a 12 × 10 Dallmeyer rapid rectilinear).

Squaring, we have 676, and to get the terms of the Dallmeyer unit we have simply to point off the 6, giving 67.6 as the standard relative exposure. With the P. S. standard, we must divide by 16, and then we get 42.25, the same relative exposure in terms of the P. S. standard.

Now, having explained the nature of the P. S. standard and Mr. Dallmeyer's proposed standard, let us try and see what advantages and disadvantages pertain to both respectively. But, first of all, let me say a word as to the claims of both with regard to being a standard of unity, representing the intensity of the ordinary quick-acting studio lenses. There has been a rather warm discussion on this point for both standards; why, I do not know, for I do not see that it matters at all which is right. For instance, of what use is it to tell a landscape photographer who is using $\frac{f}{8}$ to $\frac{f}{40}$ that in a studio (we cannot define the lighting aspect, surroundings, whether the glass of the studio is dirty or clean, and a host of other things affecting exposure) $\frac{f}{4}$ requires one second? Is there any man here rash enough that could venture to name

the landscape exposure from the data of studio lenses? And the very studio photographer himself—what cares he whether his lens is $\frac{f}{4}$ or $\frac{f}{3.162}$, &c., so long as he knows the comparative exposures required by the diaphragms belonging to his lens? It does not matter what the standards may exactly be, so long as we have a standard to enable various lenses to be used with a tolerable amount of certainty under similar conditions, and I am rather surprised that so much should have been made of this point. Besides, considering the enormous number of lenses of the "B" portrait series sent out by the firm of Dallmeyer, the intensity of about $\frac{f}{3}$ must be pretty general. At any rate, I think this point may fairly be dismissed from the argument.

We will now sum up the advantages and disadvantages of Mr. Dallmeyer's standard.

Advantages.—1. The relative exposures, as shown by the squares of the denominators of the intensity fraction, are with a glance converted into the standard terms.

2. The system is a decimal one, and as long as the base of notation universally remains 10, it is more systematic to adopt a decimal system, where it can be done with advantage.

Disadvantages.—1. The numbers run higher, in representing small apertures, than P. S. standards, in the proportion of 16 to 10.

At first sight I was inclined to include as a disadvantage the point raised by Mr. Debenham, that, to obtain the diameter of an aperture representing unity on the Dallmeyer standard, the focal length must be divided by the awkward figure 3.162, &c. I think I can presently show that this objection does not hold good. The advantage of the P. S. standard over Dallmeyer's standard is, that the numbers representing the relative exposures in terms of the standard are lower.

2. The numbers representing respective exposures have to be divided by 16, and this cannot always be done at a glance.

Now, looking at both standards fairly, I must say that I think Mr. Dallmeyer's standard certainly offers an advantage over the present one.

I think, therefore, we ought to adopt it. The pith of its advantage lies in the division by 10 instead of 16. It saves just half the trouble, as in any case we must square the denominators. There the trouble ends with Mr. Dallmeyer's standard, for we cannot count division by 10 as anything; but with the other we have 16 to divide by—not very serious, but still there it is.

Besides, though it is well known that many scientific men deplore the fact that the universal notation is based on 10; yet, while that fact remains, I think we ought to base our calculations on as much a decimal system as possible. Now we come to the disadvantage of the higher numbers in Dallmeyer's system. I think, after consideration, that this disadvantage is not equal to the advantage; in fact, the difference is not great enough to have any practical effect. I will now say a word on the objection raised by Mr. Debenham. I think he has forgotten that there is only one case where division by $\sqrt{10}$ is necessary. It is, as he points out, when an aperture is required representing the unit value itself. In no other case does the division by 3.162, &c., really occur. Besides, how rarely in these days of rapid plates we meet with a lens that would permit an aperture of the unit value, even supposing that we cared to do the optician's work and make our own unit diaphragm. Surely it does not need argument to say that the general and easy comparison of relative exposures is the point we wish to obtain, and not the making of one diaphragm of the unit value. I say one diaphragm, for in no other case does 3.162 become the divisor. We must bear in mind that any lens under the rapidity of the unit stop would not permit a unit stop to be made for it; besides, it is doing the work of the lens manufacturer to make diaphragms, and does not come under the general comparison of lenses. Once we leave unity, both systems are pretty well equally troublesome, supposing we want to make a diaphragm for No. 2 in each standard respectively. For P. S. standard we have $\sqrt{16 \times 2} = 5.65$, &c. Intensity

fraction $\frac{f}{5.65}$, &c. For Dallmeyer's standard we have $\sqrt{10 \times 2} = 4.47$, &c. Intensity fraction $\frac{f}{4.47}$, &c. There does not seem much to choose here.

In the P. S. standard we shall get whole numbers, in making diaphragms for relative exposures represented in terms of the standard by 1, 4, 16, 64, &c., as the result, extracting the square root; but as calculations are so rarely made by the photographer in this respect, it is not worth consideration.

There is another point which must not be forgotten by those who wish to make their own diaphragms; it is that in double combination lenses the diameter of the diaphragm is not the measure of the actual pencil of light transmitted by the lens, and therefore it requires an optician's knowledge to make diaphragms accurately to a given intensity.

Diaphragm making is not common amongst photographers, nor will it ever be so while we can leave this matter to those who best understand it. I think I have shown that for diaphragm making there is really nothing to choose between both standards. Should any one not think so I shall be very pleased to refer to this point during discussion. On the whole, then, I am myself in favour of altering the standard, but I hope that others more experienced than myself will discuss the matter thoroughly.

It is, of course, to the opticians we must look for the greatest advantages to be derived from a standard unit for relative exposure. If they would only co-operate we ought to have all the numbers in terms of the unit without a single decimal figure to mar the simplicity. I am not optician enough to say if this could be done absolutely, but practically I think it might be so. We had good evidence, from experienced men on the late Committee, that for all practical purposes diaphragms giving a relative exposure of twice the next largest aperture were sufficiently close. It follows from this that if we start from a standard unit the only intensities that ought to exist at all would be represented in terms of the standard by 1, 2, 4, 8, 16, and so on; and lenses having a full aperture of less rapidly than the standard should have their full apertures represented by one of the series just mentioned. Were all lenses so made, they would all be comparable with each other at a glance. By simply dividing any of the standard terms into each other—the smaller into the greater—we should at once, in definite and simple figures, see the comparative exposures required.

In conclusion, I trust that this matter will receive attention from this Society and be discussed on all its points. JAMES CADETT.

RICHMOND'S SHUTTER.

THERE are some very ingenious movements in this shutter, which was exhibited and examined with a good deal of interest at the last meeting of the North London Photographic Society. As we promised on that occasion that a detailed account of its parts would appear in this JOURNAL, we now fulfil the promise. Premising that it is very portable and tight, we subjoin a cut with explanations.

Fig. 1, front view after an exposure. To set it ready for rapid use take the elastic band A, lap it round one of the spurs B, C, D, and hook it over the pin E, as shown in Fig. 2. Pressure of the finger upon the end G of the spring catch F G will permit the band A to pull down the pin B, which raises the shutter H, as seen in Fig. 3. The band A then slips off the spur B, and acting then upon the spur J, instantaneously closes the flap, as shown in Fig. 1. The rapidity may be increased by putting more tension upon the band A by lapping it round the pin E instead of E, and still further so by lapping it once, or more, round both pins. The amount of opening will be made greater by putting the band A over C or D instead of over B, and by so doing the duration of full opening will bear a larger ratio to the whole exposure, and the picture will be more equally illuminated. If the band A be lapped over the spurs B and D twice or more, a fluttering motion will be imparted to the flap H, with a corresponding increase in the length of exposure.

By setting the detent K to keep open the spring catch F G, as shown in Fig. 4, the flap may be operated with considerable rapidity by twirling the milled head between the thumb and finger. While thus set, the shutter may be opened from behind the camera, if a cord be attached to the projecting eye N, in which case a very light counterbalance weight at the other end of the cord will enable the operator to put it out of his hand during exposure. If, while the detent is in this position, the band A be passed under the rocker, over the spur C or D, and then looped over the pin L, it will lie temporarily out of use, as shown in Fig. 5. The flap H can now be used by turning the milled head, and any exposure can be given. Focussing can be done with the shutter so arranged, more especially at such times as it is not intended to take an instantaneous picture.

In the absence of an indiarubber spring a small piece of sewing cotton, thread, or silk, may be passed over the spurs in the same manner as described for the elastic. The instantaneous exposure may then be made either by pulling the end of the thread downward, or attaching something to it as a light weight, the falling of which, when the spring catch is depressed at G, will open and close H with great rapidity.

Both parts of the elastic band must be put over the spurs, as shown at B, Fig. 3.

PHOTOGRAPHING COLOURED OBJECTS ON PLATES BATHED WITH ERYTHROSINE.

[A Communication to the Photographic Section of the American Institute.]

I FEAR that many of the members here present will not be satisfied with what I am about to show them this evening, for I do not come to exhibit reproductions of very beautiful works of art, like the paintings of Meissonier or Bougereau, printed from retouched negatives by laborious mechanical methods; neither am I prepared to show you photographs of spectrum colours. As a substitute for the sun spectrum we (meaning many practical photographers) have made our experiments with colour sensitive films upon artificial spectra, and noted our results in comparison with those of our eminent instructors in Germany and Austria.

Artificial spectra, or rather combinations of pigment colours resembling the colours of the spectrum, are somewhat difficult to contend with, as various colouring matter gives very varying results. Of several attempts made I will mention pastel colours, which show too light on the plate in every way, while those of silk or satin ribbons are indecisive, leading to many errors when judging of true colour values. Oil paint is generally too dark; aquarelle better. Of all the artificial spectra made, that of E. Bierstadt, constructed of coloured matt paper, is probably the best.

Anxious to keep pace with the progress made everywhere, and being convinced that colour sensitive methods must be eventually resorted to in sky-light and reproduction room, my aim has been to experiment with brightly coloured objects as seen in the everyday walks of life, and I have photographed chromo-lithographs and the like, selecting such as showed very brilliant and sharply contrasting colours. Before I take the liberty of laying a few of my results before you, I deem it necessary to say something of my mode of working. What has been done in colour sensitive processes since 1882 is generally well understood. Of the 144 different sensitizers which Dr. Eder has experimented with, only a few have been retained as being effective, among them the eosine group and the chinolins are perhaps the best.

When Clayton and Tailfer published their process of dyeing emulsions with eosine, they said that the same effect might be obtained by staining a ready coated plate instead of incorporating the dye with the emulsion before coating. Other European experimenters denied this, and asserted, until quite recently, that a stained or colour bathed plate could never give the same results as a coloured emulsion. For my own part I had no other means at command than to bathe plates. A few attempts to colour emulsion failed totally, and other experimenters, I am sorry to say, did not do much better, so that, as we were to consider the enormously costly imported azalin and eosine plates, there was nothing left us but to go on in the other way. As the suggestions made by A. Tailfer proved successful, I continued to work in the way proposed, and I do not think that of my many experiments I can remember half a dozen made on emulsion coloured plates. We cannot deny that bathing plates with the aid of ammonia is practical enough for all purposes. We can prepare any number of them, large or small, at a moment's notice, the operation taking but little time and requiring no extra skill, and we can expose the plate wet or dry. Stained plates keep much longer than even their advocates give them credit for, and I will show you a picture from a plate exposed thirty-five days after being sensitised for colour. I think that will do.

Of dye stuffs used we will see the effects of eosine, erythrosine, pure and when mixed with cyanin, and also those of azalin, or, more correctly speaking, if we wish to express the compound nature of the colour, chinolin red *plus* chinolin blue. Eosine has not given the generally good results claimed for it. Cyanin or chinolin, the most red sensitive substance known, is extremely difficult to work with, and has been applied as an addendum only to other matter, while for total effects, or when a variety of many colours are represented in one object, none gives better results than the erythrosine. With it we reproduce yellow in all shades quite correct, equally so green and orange, and while the action of blue and violet is retarded by the colour screen, we have red only that does not always respond properly. Not all reds copy alike. Minium I found to be the most difficult, and oxide of mercury next to it. Iodide of mercury and vermilion show much better. Carmine, lake, madder, not being pure reds, copy easy accordingly.

For general work the interposing screen cannot be dispensed with, be that a cell containing a coloured liquid or a coloured glass. I generally use a white, plane, parallel glass, coated with a collodion coloured with a tincture of Bengal curcuma, to which I add a little eosine to make it more of an orange tint. Sometimes I put a drop of cyanin solution to it to give it a greenish cast. When to use screens of different colour or shades of colour, practice will soon tell.

When the colour screen is used the time of exposure must be extended. Comparing it with that of an ordinary plate, we can say the proportion is from one to three or four; seldom greater than this.

A great difficulty occurs when judging colour brightness, and I can assure you that out of a dozen people not three will see colour alike. To some a blue appears darker, or a red lighter; to others it seems impossible to see yellow correctly. Thus I have found why so many different views on colour sensitive results can exist.

Erythrosine, giving the best general results, has become an article of trade. It is prepared in such convenient and compact form that it is available to a practitioner as well as tyro, and as long as the formula accompanying the dye is followed, there can be no doubt of brilliant success.

CHARLES EHLMANN.

Our Editorial Table.

PICTURES FROM LIFE IN FIELD AND PEN.

By P. H. EMERSON.

London: George Bell & Sons, York-street, Covent Garden.

WE have here a goodly portfolio containing twenty photogravures from negatives by Mr. Emerson, who dedicates the work to the memory of "Nicéphore" Niépce, a misprint, doubtless, for Nicéphore.

The author, in the introduction, gives as the first principle of all art a faithful adherence to nature. Wherever the artist has been true to nature, art has been good; wherever the artist has neglected nature, and followed his imagination, there has resulted bad art. Nature, then, should be the artist's standard. In meeting some objections and prejudices urged against photography because, *inter alia*, it has been called a mechanical process, he says, "Much has been written against it by incompetent photographers, who, at the same time, never rose beyond mediocrity in the branches of the art they professed. One of these has stated that its results are false in local colour. This may have been true when he wrote, but since the introduction of orthochromatic plates, and the process of photo-engraving, the accusation is no longer just. By photography the relative values can now be rendered quite correctly. Another charge brought against it was falseness of perspective, or drawing, we presume they mean. This any good photograph will promptly refute; no other evidence is required. The idea of the falseness of perspective arose from the fact that some photographers, by an ignorant use of the lens, produced distortion; and we can only say that the critic who advanced such a theory, if a photographer himself, must have been a very incompetent one, and his opinion of matters photographic therefore worthless. We know of no objections having been brought against photography as a means of artistic expression by any practical artist of genius, or even repute; and for the opinion of mediocre artists we care little."

The plates comprising the *Pictures* in the portfolio are photogravures by various firms—A. & C. Dawson, Boussod, Valadon & Co., Walker & Boutall, and the Autotype Company. We infer from the author's remarks that they are untouched, or almost so. In some of them there is evidence that they would have been improved by judicious touches of the scraper or burnisher, to bring into more prominence details which are hidden, and impart brilliancy and sparkle to the high lights. Even the roulette might have been occasionally brought into play with effect, such as in the face of the *Sticklebat Catcher*.

The little picture, *A Misty Morning in the North Sea*, which is of half-plate dimensions, is among the most beautiful, certainly the most technically perfect of the series. It is sharp and crisp, yet soft, full of detail, and in perfect gradation, and is in strong contrast to certain others in which these qualities have received minor consideration.

Sunrise at Sea is also a fine picture. *A Suffolk Dike*, perhaps the best of the series, is suggestive in its quality of Mr. Emerson's last published photogravure, *Gathering Water-Lilies*, and is free from a certain defect which is noticeable in some others, namely, the sinking of detail of important portions and ignoring any approximation to sharpness in the distance, faults which are doubtless due to the engraver, and in one or two instances to the lens.

The picture in which these negative characteristics appear most strongly is *The Gaffer*, the face of the man being lost, which we

feel certain would not have been the case had the engraver bestowed a little pains upon "cleaning" that and other portions of the picture. But, taken as a whole, the *Pictures from Life* constitute a fine collection of life scenes, which are both interesting and instructive.

PATENTS COMPLETED.

IMPROVEMENTS IN INSTANTANEOUS PHOTOGRAPHIC CAMERA SHUTTERS.

No. 9522. WILLIAM JAMES LANCASTER, Colmore-row, Birmingham.—*July 23, 1886.*

My invention relates to instantaneous photographic camera shutters for effecting what is generally known as instantaneous exposure, whereby light is allowed only to pass momentarily through the lens or exposure aperture; and my said invention consists essentially in employing an eccentric shaped shutter hung or pivoted above the exposure aperture, and before which aperture the said shutter is flirled or partially rotated from right to left by means of, or through the influence of, a volute spring secured at one end to a turning axis and at the other end to the shutter or to an enclosing casing carried by the shutter.

The spring is kept in a varying degree of tension by a ratchet wheel and pawl.

In carrying out my invention, the frame of the shutter is preferably made in two parts, or of two plates, somewhat of the shape of a fantail or the segment of a circle; and on the outside or upper plate the shutter works, and which shutter is pivoted above the exposure aperture, situated at the lower or widened-out part of the frame.

A suitable catch holds the shutter in position until exposure is necessary, and a stop or stops limit the shutter's motion when it is flirled or rotated.

Around the pivot pin or axis upon which the shutter is hung is a volute or coiled spring, secured at one end to the axis and at the other end to an enclosing case carried by and upon the front face of the shutter.

The shutter's velocity is determined by closing the coils of the spring more or less upon each other, and so increasing or decreasing the tension according to the velocity or speed which the shutter is required to be flirled in front of the exposure aperture.

The spring is kept at any determinate tension after winding or coiling by a lever pawl and spring, the former engaging with the teeth of a ratchet wheel.

Instead of employing a volute or riband spring as described, a rubber band or a flat spring (the latter acting upon a pin) may be employed.

To work the shutter, first adjust the spring to the speed required or to the length of time that the shutter shall be made to take in passing over the exposure aperture, the shutter is then turned into its normal position and held there by a spring lever catch, which on being released therefrom is momentarily flirled from in front of the exposure aperture and back again, making the exposure longer for the foreground or lower part of the picture than for the sky, which is an advantage in landscape photography.

The claims are:—1. An eccentrically hung or pivoted instantaneous photographic camera shutter, or shutter plate, which when partially rotated, or turned, uncovers and recovers the exposure aperture, progressively from bottom to top, and *vice versa*: thus giving to the bottom of the said aperture, or to the foreground or ground work of the picture, a longer exposure than the other or upper part, substantially as described and illustrated. 2. In automatic holding and releasing catch-lever mechanism, consisting of a spring arm, ear, or snag on the said arm, and rest (carried by the shutter frame) in combination with the short arm of the shutter, substantially as described and set forth. 3. Operating, turning, or partially rotating shutters, or shutter plates, by a volute or evolved spring, secured at its inner end to a movable axis (or its equivalent), and at its outer end to the shutter, or an enclosing case carried by the shutter; and which said spring is wound up, and secured at the desired tension for giving the requisite or time exposure by a screwed turn, ratchet wheel, stop, lever pawl, and spring. The parts being arranged, combined, and acting in the ways, and for the purpose, substantially as described and set forth. 4. Arresting without shock the motion of camera shutters by means of a flat or coiled spring, against which an arm on the camera shutter strikes or impresses, substantially as set forth. 5. The improvements in the construction of instantaneous photographic camera shutters, and the arrangement and combination of the parts of the said shutters, as hereinbefore described and set forth in the several figures of the drawing.

IMPROVEMENTS IN THE PRODUCTION OF PHOTOGRAPHIC IMPRESSIONS.

No. 5080. JOHN JABEZ EDWIN MAYALL, Southwick, Sussex.—*April 5, 1887.* This invention has for its object the production of permanent photographic impressions, whether coloured or uncoloured, on any suitable material. According to this invention, I first take a negative, preferably by electric light, but it may also be taken by sunlight, in the ordinary way; I then print a positive on paper, porcelain, or other suitable material, prepared as follows:—For paper I soak it in a weak solution of gelatine and lactate of iron, in

about the following proportions, namely:—Two grains of fish glue or isinglass to one sixteenth of a grain of lactate of iron, in one ounce of water, the whole being boiled and subsequently filtered. The paper, after having been immersed for about three minutes in the above solution, is dried and smoothed; this may be done by placing it between blotting-paper and submitting it to a slight pressure. I next float the paper thus prepared for about two minutes on a bath composed as follows, namely:—To about one ounce of albumen (preferably taken from fresh eggs), four grains of chloride of sodium, half a grain of bromide of potassium, two minims of glacial acetic acid, and one drop of a concentrated solution of some derivative of silicic or of hydrocarbon, of which I have found salicylic acid, prepared according to my invention, and for which I intend to apply for letters patent, to be very suitable; the whole must be beaten up into a frothy mass and allowed to settle for about twelve hours. Any tints may be given to this mass by adding the desired colour solved in a saturated alcoholic solution, in the proportions of about one minim of alcoholic solution to about four ounces of the albumen solution above described, and one minim of meconin or its derivatives; the whole is then beaten up and allowed to settle.

After floating the paper it is then dried by slow heat, and ironed on the back to make it perfectly dry and smooth. I then prepare a bath of nitrate of silver and nitrate of soda and free ammonia, in the proportions of about one ounce of water to forty grains of nitrate of silver, ten grains of nitrate of soda, and three minims of free ammonia; and when pliability of the paper is desirable, I add to the bath five drops of glycerine per ounce of bath solution.

The paper is then floated face downwards on this bath for about two minutes, and then dried in a dark room, after which it is fumigated in an atmosphere of ammonia for from three to five minutes, and is then ready for printing upon in the ordinary way. The prints, after fixing, must be soaked in a weak solution of sulphuric acid, to expel any trace of the hyposulphite of soda and well washed. The printed impression in a moist state in then mounted face uppermost on a piece of glass or skeleton frame, and, when dried, the desired colours, prepared, as hereafter described, are then dabbed on by suitable means, and slightly stumped. The dabber which I find suitable for this purpose is a pad of fine cotton wool pushed through a glass tube so as to protrude therefrom, and cut square and even at the end. This cotton wool must either be renewed for each colour or a separate dabber made as above kept for each colour.

After the colours have been applied the paper is rendered impervious to moisture by having applied to its back and front some such substance as white wax or paraffine or camphor, the print being sufficiently warmed for the purpose of the application of the wax. The colours must be stronger than are required for the final effect.

The picture is then sprayed over or subjected to an atmosphere charged with a weak alcoholic solution of salicylic acid, or some derivative of silicic or hydrocarbon, paraffine, or of any preparation of fluorine solved in alcohol to set the colour, and then it is subjected to the action of finely powdered soluble glass; this I propose to effect as follows, namely:—By placing a powdered silicon in a suitably closed chamber, provided with shelves and fitted with bellows, so as to blow the silicon powder into a cloud. The coloured picture is then put on one of the shelves to catch the fine dust of the silicon for a very few seconds, after which it is taken out of the chamber. The picture (face downwards) is then laid on a plate of glass coated in the following manner. After having rubbed the glass with a dabber of any suitable material (for which I use a ball of cotton wool covered with leather), charged with powdered silicon, I coat it with collodion, to which is added one drop per ounce of salicylic acid, and when dry I recoat it with gelatine and salicylic acid in about the proportions of one drop of acid to one ounce of gelatine, and again dry the plate. The surface of the print must now be moistened with some hydrocarbon, such as paraffine or kerosene in solution, to which is added a few drops of salicylic acid in the proportions of about two drops of salicylic acid to the ounce of hydrocarbon, and when sufficiently moist the picture is well pressed down upon the gelatine surface and allowed to dry in a warm atmosphere, after which it is stripped from the glass, and when mounted on card, porcelain, or other desired material, produces a permanent and finely coloured photographic picture.

If it is desired to have a brilliant picture, it is necessary that the entire process above described should be conducted without any delay or intermission in the various portions of the process, and in an atmosphere of increasing temperature, as if in the process the print is allowed to become chilled, a dull appearance is the result, which dull appearance may, however, be sometimes preferred.

For printing on porcelain and suchlike materials I coat the material with collodion-chloride of silver or carbon tissue on the albumen solution above described, the subsequent treatment being the same as that already described for paper.

For the production of uncoloured photographs, the process is similar to that above described, omitting the colours.

The colours I employ are ordinary colours in a dry state ground up with phenic acid and silicate of potash, or kerosene and silicate of potash in alcohol in about the following proportions, namely, one ounce of dry colour to sixty grains of phenic acid and twenty minims of silicate of potash, or sixty grains of kerosene to twenty minims of silicate of potash. In the above manipulation care must be taken to exclude all organic matters other than what are above described.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The production of photographic impressions, whether coloured or not, substantially as set forth.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The usual monthly technical meeting will take place on Tuesday next, June 28, at eight p.m., at the Gallery, 5A, Pall Mall East, when the subject will be *Camera Stands and Outfits*; also a negative on "Balagny's" flexible film will be developed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
June 28	Great Britain (Technical)	5a, Pall Mall East.
" 29	Bolton Club	The Studio, Chancery-lane, Bolton.
" 29	Photographic Club	Anderson's Hotel, Fleet-street, E.C.
" 30	Liverpool Amateur	Royal Institution, Colquitt-street.
" 30	Oldham	The Lyceum, Oldham.
" 30	London and Provincial	Mason's Hall, Basinghall-street.
July 1	Yorkshire College	
" 1	Halifax Photographic Society...	M. Manley's, Barum Top.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday, June 16, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. W. H. Prestwich presided.

Mr. A. L. HENDERSON exhibited lantern slides representing instantaneous views of horse-races brought to him by Mr. S. E. Barr, of Messrs. Porter & Coates, Philadelphia; he remarked that they were among the finest he had seen. He also exhibited some of his own views of the Jubilee Yacht Race at Southend, taken from the deck of the "Norham Castle."

Mr. J. B. B. WELLINGTON exhibited platinumotype prints of views taken at Chislehurst.

Mr. J. E. BROWN then said, The first formula I wish to bring before your notice is perhaps the most simple and, to my mind, the most effective one I have used for retouching on dry plate films. I could never see the necessity of using ten or a dozen chemicals if two would do and give results as good. Formula:—Take powdered gum dammar, one ounce; best white turpentine, *quantum suff.*; this is applied with a piece of rag or sponge. When the film appears very horny or bright I rub it with a little dry cuttlefish just before applying the medium. For a long time I advocated and used the following medium for retouching:—Take Venetian turpentine, six drachms; common resin, four drachms; mastic varnish, two drachms; spirits of turps (rectified), two ounces; benzine, about half a drachm; camphor, fifteen grains; make up to the consistency of negative varnish by an addition of white turpentine. Now I have given up this formula in favour of the first one, which is more simple to work and does not interfere with the progress of the pencil by tackiness. The next recipe I wish to bring before your notice is one for making hard negative varnish:—Dissolve half an ounce of orange shellac and half a drachm of camphor in about a pint of methylated spirit; when dissolved add about a tablespoonful of pumice-stone (powdered)—some people recommend ashes; shake well and let settle over night, in the morning it will filter beautifully clear; if too thick, add spirits of wine. For intensifying I have always found the following safe and practical:—A. Bichloride of mercury, one ounce; chloride of ammonia, one ounce; potassic iodide, one ounce; dissolve the mercury and ammonia salts in ten ounces of water, putting them both in together, and add sufficient of the strong iodide of potash solution; shake well, and make up to twenty ounces with water. B. Silver nitrate, half an ounce; potassium cyanide, sufficient to dissolve out the first precipitate; now make up this bulk to twenty ounces with water. This solution should not be used at full strength when little density is required but diluted to half. The fixed and well-washed negatives should be placed in a dish containing the A solution and gently kept in motion for a few seconds; examine from time to time until it appears quite dense, take out and well wash again until the film is an even yellow all over, then place in a dish containing the B solution, and let remain until the film becomes a beautiful olive-brown, then lift out and set aside to dry. Another formula very much used in Melbourne is a saturated solution of bichloride of mercury and iodide of potash; the negative is whitened in this, washed, placed in a saturated solution of sulphite of soda, but do not allow the negative to remain sufficiently long to reduce.

Mr. HENDERSON liked Monckhoven's intensifier, consisting of iodide of mercury followed by silver.

Mr. A. COWAN said that that was Monckhoven's formula.

Mr. W. M. ASHMAN exhibited a negative intensified with iodide of mercury, followed by sulphite of soda.

Mr. J. J. BRIGNSHAW said that the railway companies north of London had combined not to give reduced fares to public associations.

Mr. WELLINGTON stated that the Photographic Convention at Glasgow could be reached by boat and train from London via Leith, first-class fare there and back 19s.

The proceedings then closed.

CAMERA CLUB.

On Thursday evening, June 16, a short paper, entitled *Film Staining and Halation*, was read by Mr. Lionel Clark. Mr. F. Macchell Smith occupied the chair.

Previous to the address, Mr. J. F. Roberts exhibited a compact detective camera introduced by Messrs. Watson & Sons, in which the plates were dropped into their place from the double holders in which they were stored. The focus could be adjusted by means of a movement of the handle by which the apparatus was conveniently carried. A rapid rotary moving shutter was fitted to give the exposure.

Mr. W. A. GREENE showed some experiments in printing-out positive images by long exposure on Eastman negative paper, and

Mr. D. P. RODGERS drew attention to some strong paper envelopes just introduced, which were made to sizes for storing different negatives in, and were prepared outside for the entry of particulars.

Mr. CLARK then gave his lecture, and in discussion

Mr. RODGERS said the slowing effect of litmus in staining might not be of great importance, seeing the rapidity of plates as now made, but

Mr. CLARK stated that it would appear to have the effect of reducing them all to a standard rapidity not many times faster than wet plates.

Mr. J. TRAILL TAYLOR explained a method (by piston and cylinder) by which he had obtained a clear turmeric solution. He had observed that in looking out into the light from Fingal's Cave the phenomenon of the interference of light or halation appeared at some of the openings and not at others, where, presumably, the atmosphere was clear of dust or vapour. In referring to the backing of plates, he described a simple but pretty experiment, showing halation to be obviated by a substance being brought into optical contact with the glass.

Mr. H. H. O'FARRELL asked why tinctures were not used in isochromatising plates.

Mr. HYSLOP stated that the colour did not seem to enter the film so well or homogeneously; some of the dyes would not dissolve in alcohol and some in water, but required half-and-half. He had found some difficulty with cyanine as with alcohol; it gave a small deposit. He found the fuchsine he had used slowed the plates, and it was a substance it was extremely difficult to get rid of from the films it was used in.

Mr. A. PRINGLE said in the early days of gelatino-bromide plates the use of a backing was nearly always adopted, but when iodide was introduced there was less necessity for such treatment. His experience was in agreement with Mr. Hyslop's that iodide plates treated with isochromatising solutions were as good as bromide plates treated similarly. He had not, however, found his samples of fuchsine have any slowing effect upon the plates treated with it, though there was some difficulty in dissolving it.

Mr. CLARK had developed some isochromatic plates with oxalate, and they retained their red non-actinic colour throughout. He thought that the most important point was the use of tinctures in these processes, so as to secure rapid drying. Possibly the difficulties met with in regard to making alcohol take up the colour were to be overcome. It took up the colour more slowly, and he thought that by a very long digestion in a warm room the object would be obtained.

The proceedings terminated with a vote of thanks to Mr. Clark for his address.

Club excursion for members and friends to Marlow on Saturday, June 25.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting was held on Tuesday, the 7th instant,—The President, Mr. T. S. Yeomans, in the chair.

After routine business, final arrangements were made for the Society's excursion on the following Thursday, after which a paper was read by Dr. MORRISON on *Lenses*, with special reference as to which is the best lens for an amateur to possess.

A discussion afterwards followed, the general verdict being that a rectilinear was the most preferable type of lens.

A vote of thanks was given the lecturer for his paper.

The excursion, the first of the year, took place on the 9th instant to Haddon Hall. Owing perhaps to the President's kindness in offering a special prize for the most original and artistic picture taken on this excursion, a good muster of members and friends was made. The interiors of this old mansion claimed much attention, for some members elected to expose their plates on interiors only, as the wind by this time was high, and exterior work, even without foliage, was extremely difficult. Twelve cameras were at work, and in all one hundred and thirty plates and films were exposed during the day, this being an average of nearly eleven per camera.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY

The monthly meeting of this Society was held on Tuesday, the 14th instant, at the Masonic Hall, Cooper-street,—The President, the Rev. H. J. Palmer, in the chair.

The following were elected members:—Miss E. J. Stanley, Messrs. Thomas Hall, John Lay, and T. W. Markham.

The Council presented a report with regard to the desirability of starting a quarterly magazine or record of the proceedings of the Society, to act as the official organ of the Society, and recommended the formation of a guarantee fund for the purpose, and requested members willing to subscribe to such a magazine to give in their names to the Hon. Secretary.

The several leaders of the outdoor meetings or rambles gave a report of the success of the rambles that have taken place, and particulars of the ones arranged for during this month, namely, to York, Chester, and Alderley.

Mr. GEORGE H. B. WHEELER read a paper on *The Improvement and Retouching of Landscape Negatives*. Mr. Wheeler began by speaking of the great number of negatives that from divers causes, preventable and otherwise, do not print as we wish, and are therefore cast on one side and form a skeleton in the cupboard, to which we often turn with vexation of spirit. These he advised the members to bring out and either end or mend them. Passing briefly the commoner faults of thinness of the image and over density, with their causes and remedies, Mr. Wheeler proceeded to describe the methods employed to improve negatives untouched, and improved prints from which pasted to one mount were handed round for the inspection of the members. The prints showed how over dense portions had by local reduction with chloride of lime been made to print, how by retouching and strengthening the foreground the picture was artistically improved, and how by marking at the back with vegetable parchment (sold for jam-pot covers) worked upon with pencil and stump a negative having extreme light and shade can be improved. Mr. Wheeler exhibited a home-made retouching desk of very simple construction, and, in his remarks on retouching, said that a desk was essential to comfort and good work, that the Paragon Retouching Medium was the best he had tried, and that HB and B pencils are the best to use for landscape negatives.

Mr. S. D. MCKELLEN exhibited and described his patent camera with its newest improvements, including his new focussing screen protector, which does

away with the use of a focussing cloth. This protector can be fitted to any camera, and was much admired. Mr. McKellen also exhibited his patent mechanical rocker and McKellen and Muth's auxiliary view meter and focuser. At the *conversazione* held after the meeting the tables were literally covered with photographs, the result of the Easter and Whitsuntide holidays and the Society's rambles. Prints were exhibited by Messrs. Fildes, J. G. Jones, G. Wheeler, J. Davenport, C. Dawson, W. Berry, J. A. Furnival, Guilford, Smith, Hutchinson, and Whitham.

Correspondence.

Correspondents should never write on both sides of the paper.

A NEW AND NOVEL OBTURATOR.—A POCKET CAMERA ON THE OPERA HAT PRINCIPLE.—A DETECTIVE CAMERA BY M. DARLOT.—M. BARDY ON M. SCOLA'S PREVIOUS COMMUNICATION.—CAMERAS WITHOUT LENSES.—TONING PLATINUM PROOFS.—M. BALAGNY ON REVERSIBLE FILMS.—A CONCOURS AMONG THE MEMBERS.

M. DE LA BAUME PLUNIVEL presented a new obturator, or instantaneous shutter, upon a principle which, I think, has not been seen before, at least in France. I imagine that if it be found good in practice many advantages can be obtained that are impossible with others now in the market. Firstly, extraordinary rapidity; secondly, little or no change in the diaphragm box of the lens; thirdly, a larger opening than any other obturator of equal size; fourthly, a great economy in manufacture. These are the principal advantages I could see in this new idea, that is, if practice will show that it has not a disadvantage which will neutralise all the value of the idea.

Any one can make one for himself. Let him take the large diaphragm of his lens and fit in it another piece of brass exactly of the same thickness. Across the centre of this disc is placed a knitting needle, which is soldered firmly to it; a little thin brass bearing is put on the lower part and another on the top of the hole in the diaphragm in order to fasten the knitting needle, which now forms an axis to the diaphragm. We have now a sort of valve not unlike that of a waterworks company. By turning the top of the axis the disc opens or shuts the hole at will. Now for the disadvantage. When the hole is full open, the axis and the thickness of the disc is always there, and if it does nothing else it hides a certain number of rays, and in consequence dims the light. This line of obstruction, if I may call it so, being in the middle of the lens, is not reproduced on the ground-glass, and therefore its inventor says "it is of no consequence." This remains to be proved. The constructor had attached a kind of racket work to the top of the axis, by which means it can be set for working; it is started off by means of a pneumatic ball, and has certainly a pretty appearance. Many proofs were shown of moving objects taken with this new obturator, and altogether they were as good as the generality of such pictures.

The same gentleman presented a pocket camera, the new feature being that it is very light, the bellows being of silk, held together with the steel springs of an opera hat, and opens and closes in the same manner as that necessary object of wearing apparel. It might cause some annoyance to its owner in these peaceful times of dynamite, &c., as it opens with a certain amount of noise.

M. Darlot, the highly-esteemed optician, presented a detective camera most elaborately got up—in appearance, a gentleman's leather dressing-case. The lens is only uncovered at the proper moment by touching a spring, and the dark slides being in the interior no fear of fog from light need be feared. A sort of camera obscura is placed on or in the top of the box, so that the object to be photographed can be followed and seized at the proper moment; this is done by pulling one of the feet. The instantaneous shutter is thus set at liberty. As it is automatic, no adjustment as regards focus is required. Altogether, a very pleasing and complete apparatus for a tour.

M. Bardy criticised the last communication of M. Scola, and told the members to beware how they placed their confidence in that colouration for their dark rooms. He had examined a piece of glass coloured by the system of M. Scola by the spectroscope, and found its absorbent power of the rays of the spectrum to be far inferior to that of the yellow glass which can be found on the market; "Except," said he, laughingly, "it be left a certain time to light, when it becomes as transparent as a piece of varnished sheet-iron, such as is used for the ferrotype, which it resembles. The silver nitrate," said he, "changes daily until it becomes as opaque as the piece here before you, which, by-the-by, was left by M. Scola."

Is it not that M. Bardy got hold of a piece of glass coated with gelatine and silver nitrate which had not been put into hyposulphite of soda as soon as the proper colouration had been attained? As preconceived by M. Scola, this continuation of the action of light might then be accounted for.

Some proofs were shown obtained in a camera without a lens, which were very good—exposure varying from fifteen seconds to three minutes. If I remember right, our mutual friend Henderson exhibited some proofs obtained by him to the London and Provincial Photographic Association, stating the size of the hole with which he worked, &c. I bear upon this point as several amateurs here are enraptured with their success, and are bringing it *à la mode* as they say its advantages are numerous, necessarily

under certain conditions. Firstly, no expense for the purchase of a valuable lens; secondly, no fear of its breakage, as well as that of the ground-glass, the latter being wholly discarded, as every object is in focus at the same time; thirdly, a larger angle can be embraced than by the generality of lenses (90°), which permits photographs of objects to be obtained which formerly we hardly hoped for—such as the image of a church in full situated in a narrow street, the interiors of monuments, &c., which can now be obtained by this means, thanks to the rapidity of the gelatino-bromide of silver process; fourthly, which is not its least advantage, no deformation—everything is mathematically correct, thus rendering enlargements possible.

M. Vidal drew the attention of his pupils to the fact that positives obtained upon Eastman's paper could be rendered more permanent and more agreeable to the eye by toning them in a solution of bichloride of platinum.

Water	2000 parts.
Bichloride of platinum	1 part.
Hydrochloric acid	25 parts.

W. Vogel, jun., has experimented, and proposes to plunge the proofs from fifteen to twenty minutes in the following solution:—

Water	1000 parts.
Chloro-platinate of potassium	1 part.
Hydrochloric acid	10 parts.

The proofs are then well washed and placed in a solution of bichloride of copper—fifteen per cent; they are then washed in a solution of alum slightly acidulated with hydrochloric acid. When washed they are ready to be mounted.

I must add that M. Vidal obtained better results with the single bichloride of platinum than with the composed salt as recommended by Herr Vogel.

M. Nadar is enchanted with the formula as given by M. Vidal, which is easy in practice and economic in the long run. I had the pleasure to visit the sanctum of M. Nadar the other day in company with two English photographers, Mr. Protheroe, of Bristol, and Mr. Seannell, of London. M. Nadar showed us some magnificent work obtained upon Eastman's positive paper toned by Vidal's platinum bath.

M. Balagny presented some very fine fatty-ink pictures, which he had obtained from his film negatives. This gentleman made a very long dissertation, the substance of which, as far as I could glean, may be summed up as follows:—Method to render a stripping film suitable for fatty-ink printing—Take a sheet of glass, talc it well, then plunge a sheet of gelatine (such as are easily found in the market) into a tray of water, let it expand for a few minutes, then gather it up upon the talced glass plate and with a squeegee make it adhere to the glass plate. Now take the paper negative, damp it, and lay the image upon the gelatine—the squeegee can be used to obtain a perfect contact. As soon as the whole be dry the paper will peel off the image and the image will leave the glass. We have now obtained a supple film from which can be printed off albumenised proofs, or a contact impression upon bichromated gelatine for fatty-ink impressions.

M. Fabre gave his opinion upon the measuring of the rapidity of rapid shutters.

The Chairman informed the members that it had been decided that a concours of photographic proofs should take place among the members, and that different medals should be awarded. PROF. E. STEEBING.

59, Rue des Batignolles, Paris, June 5, 1887.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

To the EDITORS.

GENTLEMEN,—Allow me through your columns to announce that detailed programmes of excursions and local arrangements of the proceedings at Glasgow for the week commencing July 4 are now ready, and will be forwarded on application.

The excursions include visits to the Falls of Clyde, the Trossachs, Loch Lomond, Loch Long, Yacht Regatta at Largs, Loch Fyne, and Edinburgh.

I have pleasure also in announcing that the Hon. the Lord Provost of Glasgow has kindly consented to open the proceedings on the evening of the 4th proximo.—I am, yours, &c., J. J. BRIGGSIAW, Hon. Sec.
128, Southwark-street.

SENSITISING OF AZALIN PLATES.

To the EDITORS.

GENTLEMEN,—Allow me to correct a misunderstanding of yours with regard to the sensitising of azalin plates with ammonia by E. Vogel, jun., of Berlin.

It is not the *restoring* of the sensitiveness of bath plates that Vogel has tried; his experiments were made with the object of increasing the sensitiveness of emulsion stained plates which are, as is well known, much slower than bath plates, but more regular and more reliable. These emulsion stained plates have their sensitiveness increased by immersion in a two per cent. solution of ammonia, and are rendered thereby four to five times more sensitive.

This result, Vogel expects, would also be obtained on other kinds of orthochromatic plates.—I am, yours, &c.,
J. R. GÖTZ.
19, Buckingham-street, Strand, London, June 20, 1887.

CREAM TINT ON PAPER.

To the EDITORS.

GENTLEMEN,—Referring to your report of the proceedings of the London and Provincial Photographic Association on the 9th instant, I beg to explain that my remark as to a cream colour on Eastman bromide prints was confined to a few samples. I said I had found some Eastman paper to give a creamy tint. As a matter of fact, one packet of a dozen sheets only showed the tint.

I do not know how the tint got there (it puzzled me at the time and puzzles me still), but I should like to see more of it, for it struck me as very pleasing.—I am, yours, &c.,
ANDREW PRINGLE.
Camera Club, June 17, 1887.

THE RIGHT TO THE NEGATIVE.

To the EDITORS.

GENTLEMEN,—Since Mr. T. Coan, of 50, Cumming-street, Pentonville, N., has done me the honour to notice my letter which appeared in your issue of the 10th, and as he comes forward as the champion to defend and maintain the photographers' right to the portrait negative *irrespective of the will of the sitter*, perhaps you will allow me to ask of him the favour of answers to the questions my letter contains, and also to give me, *consecutively numbered*, the reasons he has to justify his claim to that right. These done, I shall, if he wishes, with your permission, discuss the question at issue with him. The ground I take is that so ably sisted by your correspondents, "J. F.," Mr. Dutton, and "Mac."

One more remark. I am an economist, and never indulge in anything till I am sure I can afford it. I ^{ends;} ^{no} advice, but I hope, with reference to wit, or an attempt at wit, ^{ends;} ^{will} take this hint as suggestive.—I am, yours, &c.,
MILLIE.
Newcastle-on-Tyne, June 18, 1887.

MEDAL AWARDS.

To the EDITORS.

GENTLEMEN,—Mr. Pike's note in your issue for June 17 points so directly to me, that I hasten to assure that gentleman that I am not "No. 8." Now, however, that I am writing, I may state that I greatly endorse the sentiment of "No. 8." in "Exhibitor's" letter.

I think there are many reasons to consider exhibitions and medal awarding unsatisfactory, not the least being the possibility of "wire-pulling," and other work done "behind the scenes" which, with however much "gusto" it may be denied, yet, in many cases, only too palpably exists, and rains down medals on management rather than merit. It is open to question, too, if judges are always capable of judging. From my experience, I know not. I take it, that given technical excellence, the art qualities of a photographer are of greatly the first consideration in approving his merit, and yet nineteen out of every twenty photographers are as innocent of real art knowledge as a new-born babe; they can appreciate photographic art well enough, doubtless—a production often, alas! far divergent from the actual picturesque; its accomplishment is their aim and its achievement brings with it a soothing contentment, quite undisturbed by any excelsior-like qualms as to the "great unexplored beyond."

Then, who shall speak that judges are always above the petty wails so insuperable from frail humanity? I have thought that painters should judge photographs, welcome and nurture its infant art-life for its own art sake, and so lead its votaries into a better knowledge of what to strive for; but I had not counted that an unworthy jealousy would cause them, with their broad, unlimited plains, to grudge the tiny pasturage of the puny photographer, to ungenerously deny their scanty heritage, and trample it down to the lower level of bare photographic merit.

Doubtless, judges are much hampered by the present foolish system of assigning so many awards to portraits, so many to landscapes, and an odd one *sometimes* thrown in, by the way, for what is really the most meritorious, most difficult, and most possible of artistic achievements embraced in the term *genre* pictures. Here the parent society shows a very excellent example in sensibly giving the judges a *carte blanche*, no limitation to class, but only to bestow awards where, in their opinion, sufficient merit justified it.

In this, at least, one wrong is removed, and, all things considered, I think the Photographic Society of Great Britain might rest content that they have adopted the most perfect plan without experimenting or doing away with awards which, I fear, would smack too much of racing without a goal.—I am, yours, &c.,
LYD. SAWYER.

6, Novaine-road, Newcastle-on-Tyne.

Exchange Column.

Will exchange an interior and exterior background, eight feet square, for similar sizes. Seavey's preferred. With cash adjustment.—Address, M. AUTY, 20, Front-street, Tyne-mouth.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

DESMOND HILL.—The formula appears perfectly correct.

W. J. BROWN.—Four hundred and eighty grains to the ounce.

A. FREYER EVANS.—We shall be pleased to hear the results of your further experiments.

E. J. HUGHES.—1 and 2. Write to the maker of the plates in question; he will supply the desired information. 3. Yellow glass which is suitable for a dark lantern, will be much too non-actinic for a colour screen in orthochromatic photography.

SAMUEL HOLLINGSWORTH asks for a recipe for tannin plates, which shall be as rapid, or more so, than wet collodion.—Let him use a bromised collodion, eight or ten grains of a bromide salt (say ammonium) in each ounce of collodion; excite in a sixty-grain bath, wash and coat with a solution of tannin fifteen grains to the ounce of water, developing with the usual alkaline developer.

A. S. C.—A good artificial instantaneous light, of great actinic power, is made by mixing together four parts of chlorate of potash, two parts sulphide of antimony, one part of sulphur, and one part of magnesium filings. The ingredients must be reduced to a fine powder before they are mixed together, and the mixing should then be done with a bone spatula on a sheet of paper. If they were to be rubbed together in a mortar a violent explosion might result.

J. B.—The reason of the delicate tones in the carbon prints washing away during the development is no doubt due to the tissue being in a too soluble condition. Remedy: keep it longer before using. It is possible that the trouble may arise from the water employed for mounting the exposed tissue or the glass was not sufficiently cold for the purpose. Its temperature should never exceed 60° Fahr. If it be warmer than this, the temperature should be reduced by the addition of a lump of ice.

HENRY W. BENNETT writes: "I should esteem it a great favour if you could give me a reply to the following in your 'Answers to Correspondents.' I have a lens of the rapid rectilinear type of the following dimensions: Equivalent focus, eight and three-quarter inches; diameter of lenses, one and a quarter inches; focus of front combination, nineteen and a half inches; focus of back combination, fourteen and a half inches; distance between lenses, one and a half inches. 1. Can you tell me from these data what the distance between the lenses should be so that it may work well as a wide angle lens? I intend having a short mount made, so as to use it as such when necessary, to include a wider angle than usual.—2. When using the single combinations of doublet lenses alone for landscapes I find it impossible to get good definition unless a very small diaphragm is used; in the lens in question about $\frac{1}{16}$ for the front and $\frac{1}{32}$ for the back. Is this due to the lenses being so small in diameter in proportion to their focus (one and a quarter inches diameter, nineteen and a half inches and fourteen and a half inches focus respectively)?—3. If not, could it be improved by the alteration of the position of the stop when using single lenses alone?—4. When using the single lenses alone would it be better to have a new mount made in which the position of the diaphragm were modified?—5. If so, what would be its best position, or how could I determine it?—6. Could you tell me of a good work on this subject, not too expensive: English, French, or German?"—To the foregoing we give a general reply. The distance at which lenses should be mounted apart depends entirely upon their curvature and not alone on their foci; hence the impossibility of our giving the length for a mount to adapt it for wide angles. But let it be understood that when using any given size plate no alteration of the mount would enable any wider angle to be included on that plate, although it would give a larger circle of illumination and thus permit of the employment of a larger plate. To use a single combination of a doublet successfully, the diaphragm must be removed from the lens to an extent equalling nearly double that required when employed in combination. It will not be necessary to have another mount made if this be borne in mind. Precisely the best position can only be determined by experiment. The best work on photographic optics—indeed, the only one—is that of Monckhoven, published in 1866; but this was prior to the general introduction of lenses of the type you are employing. If you bring the lens to our office we shall be better able to advise.

RECEIVED.—Hinton & Co.'s Photographic Price List.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, June 29, will be on *Aids to Exposure*. Saturday outing at Lea Bridge. Trains nearest two o'clock from Liverpool-street.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1417. VOL. XXXIV.—JULY 1, 1887.

BACKING PLATES TO PREVENT HALATION.

We are very glad to find some attention being given to a subject which, though one of prime importance, has nevertheless met with but scant attention at the hands of the general body of photographers—we allude to the prevention of "halation." We need not hark back to the days of the dry plates of old when halation and its remedy—backing the plates with some coloured body—was perfectly well known; the effect has been chronic ever since, though brought into greater or less prominence according to circumstances and to the particular kind of plate which happened to receive popular favour. Suffice it to say, it is a familiar enough effect, long ago shown to be caused, in the main, by reflection at the back of the plate of a certain proportion of that portion of the light that formed the image, but was not entirely absorbed by the film. This light would not pass through the film in the unbroken ray it arrived there, but would be scattered in all directions, and, hence, reflected in part, when it arrived at the back surface of the glass, as a halo or cloud roughly following the shape or contours of the illuminated patch of film.

The cause of this reflection cannot be more succinctly described than in the words of Mr. Glazebrook, in his work, *Physical Optics*. He says, "When a wave of light in one medium is incident on the surface of a second and different medium, part of the light is reflected back into the first medium, part is refracted into the second, each according to definite laws."

In the case we are considering the two media are glass and air. The problem is generally considered to be how to get rid of this second medium from between the back of the glass and some substance to be there placed which will not reflect light. When this effect is achieved the particular substance is then said to be in optical contact, and is commonly termed a "backing."

Before entering more fully into the practical aspects of this subject, we take the opportunity of drawing attention to a misapprehension that pervades the common way of looking at this matter, and which is apt to lead to disappointment when the work of negative making with the aid of backing is undertaken. For the entire prevention of the reflection of light upon the film we require a plate of glass with perfectly plane surfaces—the film side and the uncoated side—and, likewise, a substance which is a perfect non-reflector. The surface of the glass of the average dry plate is very far removed from the perfection of planitude, and we are not acquainted with any substance which absorbs every ray of the spectrum.

It therefore follows that, though our plates be provided with a properly applied backing, we cannot in the nature of things

expect that no reflections will come to our film, and that we shall be able to entirely avoid halation, as, to some degree, whatever pigment we place at the back of our plate, and however we plan to have it in optical contact, some reflection must occur.

There cannot be a doubt that the film itself acts as a light diffuser within its own texture, the extent to which this diffusion takes place laterally not having, within our knowledge, formed a subject of investigation. It is extremely probable that its effect is of the very slightest when compared with the reflection at the back of the glass; still, it is a factor in the total amount of light in wrong place. A more important factor it appears to us is the light scattered by irregularities of the surfaces of the film, and of the glass which forms its bed.

If photographs could be with usefulness taken on black glass, these latter defects would be the only ones to interfere with perfect freedom from blur; as, whatever light passed some little depth into the glass, it would be entirely absorbed, and the opportunity of reflection would not occur, except, to a slight extent, at the plane of juncture of film and glass, and here, it is scarcely necessary to observe, it would be absolutely innocuous, if indeed it were not a help.

If, taking a hypothetical case, we could fuse into the glass itself a number of particles of some black body, the effect would be the same as the pigment in optical contact. Again, if the glass were of such a colour as only to allow rays of no actinic power to pass through, no halation would occur, as, though reflection at the back would take place just as usual, it would be reflection of non-hurtful rays. Also if it were possible to obtain a "flashed" glass—that is, a colourless glass with a coloured skin, so to speak—the flashing to be such as would only allow non-actinic rays to pass, we ought to expect absence of halation, and we could then get a practically usable negative by dissolving away the flashing by hydrofluoric acid after the negative was produced. Such a plan, however, for everyday photography is entirely out of the question; but we have a method available, not included in the first scheme of pigment backing we have already spoken of, which we may now describe.

It consists in the substitution for this supposititious "flashing" of a skin of another kind, the details of which were worked out by Captain Abney some years ago. He applied to the back of a glass, and in optical contact with it, a coloured skin which only allowed harmless rays to pass through.

The method of doing this was simply to coat the back of the dry plate with a collodion coloured in such a manner as to carry out the above idea. His plan was to dissolve aurine and roseine in ordinary plain collodion, and then to pour the

coloured liquid on to the plate and allow to dry. The method is both simple and useful; but, bearing in mind the principles governing the reflection of light as described in the first part of this article, we find the light wave in one medium (the glass) to be incident on the surface of a second (the collodion), and so must expect part of the light to be reflected back "according to definite laws." But those definite laws show that if the second medium possess certain qualities, it acts practically as though the two media were a homogeneous whole, and the second then would not be a "different" medium. The action exercised upon light passing through transparent bodies is estimated in the term "index of refraction," and when two bodies whose indices of refraction are identical are in optical contact, they (in the main, though there are subsidiary discrepancies not necessary here to describe) act as though one homogeneous medium. Almost the whole question, therefore, of collodion coating centres upon the index of refraction of the collodion itself. We have no data at hand from which we can ascertain this index, but we should believe it to be very little different from that of glass.

In this survey it will be seen that a choice is offered of many ways of backing a plate to avoid halation; but, as theoretical modes of treating a practical question must always be put to the test of practice, we are able to say that we have been making a large series of experiments as to the best, simplest, and most practical way or ways of performing this operation, and we shall be pleased to give our readers the benefit of our experience and the conclusions we have arrived at in a forthcoming number.

REDUCING NEGATIVES BY MEANS OF CHLORIDE OF LIME.

At the last meeting of the Photographic Society of Philadelphia, Mr. Fassitt is reported to have moralised on the iniquity of publishing "such impracticable recipes" as that given in an article in our last ALMANAC by Mr. H. Hall for a simple process for the reduction of negatives.

In justice to ourselves, no less than to Mr. Hall, we would point out, however, that the recipe is not at all impracticable, but that the failure of Mr. Fassitt is due to his non-acquaintance with the fact that in England, at least, a liquid chloride of lime, or a concentrated solution of the crude salt which passes under that name, is an article of commerce. It is quite possible that such a preparation may be unknown in America; but even if such be the case, one would have thought that upon reading Mr. Hall's instructions, Mr. Fassitt might have suspected that chloride of lime in the liquid form was intended, for the directions are to "dilute ordinary chloride of lime with half its bulk of water."

In the first place, the mixture of a solid substance with water is not "dilution," but "solution;" and in the second, the process that entailed the trouble of accurately estimating the "bulk" of a given quantity of powdered chloride of lime of commerce would scarcely be described from a photographic point of view as a "simple" one. Had it been intended that the crude hypochlorite of lime or "bleaching powder" was to be employed, it would have been directed to mix it with a certain proportion of its "weight" of water, if a definite quantity or volume was not mentioned, for the term "bulk" is seldom or never used chemically in connection with solids. The preparation alluded to in the ALMANAC article is a strong solution of an alkaline hypochlorite, similar in character to Labarraque's solution, Eau de Javelle, and Holmes's Ozone Bleach, but dif-

fering from them in that its base is lime instead of potash or soda.

We make this explanation in order to clear Mr. Hall and ourselves from the unjust charge of causing harm by the publication of impracticable recipes. If Mr. Fassitt himself had applied some little thought to the published formula, he would have been saved the trouble of publishing his condemnation of his own reading of it.

THE Queen's Jubilee has come and past; the *fêtes* in commemoration with the event have all been favoured with the proverbial "Queen's weather." Perhaps at no previous period have so many outdoor subjects been portrayed by photography in a single week as on this occasion. Not only in the great metropolis, but in every provincial town, village, and hamlet there have been rejoicings, mementoes of which have been portrayed by photography, every one of which will be of interest, particularly as time wears on. Had photography been in existence at the time of the last Royal Jubilee, pictures of the procession and other events would now be interesting curiosities as well as commercially valuable. Although the weather was all that could be wished for in London, and cameras of all sizes and shapes, as well as every conceivable form of instantaneous shutters, were brought into requisition, a considerable number of pictures of the royal procession are marred by the flags, bannerettes, and other decorations of the different thoroughfares hiding a large portion of the pageant from view. At very few available points could the whole cavalcade be seen at once, and where it could it was, in the distance, often too indistinct to show in a photograph. This was owing to the haze which prevailed, arising from the dust raised by the vehicles from the sand with which the roads were strewn. Excellent negatives of the local Jubilee *fêtes* have, we learn, been secured in most, if not in all, of the provincial towns and villages.

THE Jubilee may well be reckoned a red letter event amongst photographers, stationers, and printsellers. Those who were fortunate enough to possess negatives of Her Majesty have been busy in supplying impressions therefrom in almost every conceivable style and size. Engraved portraits of the Queen at the time of her coronation, or engravings of the ceremony itself, which a year or two back would only have realised a few shillings, if they found purchasers at all, have recently sold for as many pounds. A large proportion of the portraits sold by the stationers are mechanical prints—Woodburytypes or collotypes—many of them printed abroad. Large orders for collotypes of the Queen we know were some months back sent to Germany for execution. When will England be able to compete with Germany in collotype printing?

HERE is a good story of Jubilee week. Time, after Her Majesty had left London; scene, a quiet West-end street; *dramatis persone*, an Amateur Photographer (who had gone to some expense in decorations) in conversation with friend at next door. Enter to them Itinerant Photographer with quarter-plate "box" camera, bent on photographing the decorations. I. P. "If you please, gentlemen, could you tell me the name of the party that lives next door?" Friend (winking at A. P.). "I don't think you need go there; an amateur photographer lives in the house." I. P. "Oh! those are the parties we are most successful with; they likes to have our work as samples what to aim at. Oh! yes; the amateur is not above takin' a lesson." Friend. "Well, the gentleman's name is Jones." I. P. "Thank you, sir." N.B.—Application was duly made, and after the door had been peremptorily slammed in Itinerant's face, A. P. (sadly), "I'd like to wring that fellow's neck!"

BICHRIMATE OF POTASH has now become an important salt in connection with photography, and on several occasions we have alluded to its pernicious action on the skin and its poisonous properties generally, but like most persons we were not aware that it was explosive. According to the *Standard* the lamentable catastrophe at Manchester last week was caused by an explosion of bichromate of potash. Other papers have given different substances as the cause of

the disaster, and Messrs. Roberts, Dale, & Co., on whose premises the explosion occurred, state that no explosive materials are made or kept on their premises. Whatever may have been the cause of the mischief, our non-chemical readers who use the salt need not be alarmed, as bichromate of potash has no explosive properties whatever.

MANY of our readers will remember that some seven years or so ago a "Colour Photographic Company" commenced business in a handsome establishment at Knightsbridge, and under very auspicious circumstances, many of the shareholders being influential personages amongst the "upper ten." After about twelve or eighteen months the affair collapsed, as such affairs hitherto have done. When the Company first started, some of the daily papers, as many have done recently, stated that a process had been discovered, and was being worked by the Company, whereby photographs could be taken in natural colours. The directors of the Company, to their credit, at once wrote contradicting the statement, and denying that it was made either with their sanction or knowledge. Such a correction as that would not be out of place now—late as it is—with reference to announcements which have recently appeared in several of our daily contemporaries.

GREAT dissatisfaction is being expressed with regard to the new coins just issued. Whatever may be opinions as to the design, there is no denying that the portrait is very unlike any of the published photographs of Her Majesty. For what reason the portraits on the coins should not be likenesses it is difficult to conceive. It is to be hoped that in the next issue, if there is to be one, that the portrait will be taken from one of the latest photographs.

AN excellent style of mounting and framing gelatino-bromide enlargements is to mount the pictures on linen, in the same manner as engravings are mounted. The linen, sufficiently large to allow of a margin of about three inches round the picture, is strained on a stretcher. It is then covered with fine white paper, and on this the picture, after being neatly trimmed, is mounted. We recently saw a pair of highly finished enlargements on matt surface bromide paper framed in this manner, and they possessed a far more artistic and refined appearance than they would have done had they been in the usual cut-out cardboard mounts. They more resembled good engravings than ordinary photographs.

ANENT the leader *Collodion* versus *Gelatine* last week, it may be mentioned that the wet collodion process still holds its own for many purposes. Photo-lithographers and photo-etchers employ it almost exclusively; so do most persons working photo-mechanical processes, on account of the vigour of the image, and the clearness in the shadows obtainable. Equal qualities in these respects may, however, be secured with gelatine plates, but they must be made specially for the purpose. Such plates will necessarily be very slow as compared with ordinary ones, although they will be much quicker than wet collodion. Excessive rapidity, so much sought after by most artists, is one of the reasons why dry plates are so little employed for the above purposes—clearness of shadows, as a rule, being incompatible with extreme sensitiveness. It might be worth the consideration of dry plate makers, as to whether it would not answer their purpose, commercially, to supply plates specially made for copying—slow ones—say, two or three times, only, as sensitive as wet collodion. Plates of this kind could easily be made, and if they were developed with ferrous oxalate, they should yield shadows quite as bright and clear as those obtained on collodion. A few years back photographers would have gone into ecstasies over dry plates, for ordinary work, which were but two or three times as rapid as wet; surely they will now be content with plates of similar rapidity for copying purposes, provided they could with them obtain as satisfactory results as with collodion.

THE PHOTOGRAPHERS' CONVENTION IN GLASGOW.

As stated last week, the Convention, which opens its week's *séance* on the 4th of July, is destined to be highly successful.

On the evening of the day mentioned, the proceedings will be opened by the Lord Provost of Glasgow. From the subjoined list it will

be seen that excursions have been arranged with great skill, and that these embrace the choice artistic and historical parts of Scotland, at fares surprisingly low. Roughly speaking, the days are to be devoted to sight-seeing, and the evenings to the scientific and literary department of the Convention. Hotels, postal, and telegraphic communications, have all been arranged by the energetic Local Committee. Those desirous of details other than we here subjoin should apply to Mr. J. J. Briginshaw, 128, Southwark-street, London, S.E.

SYNOPSIS OF THE WEEK'S PROCEEDINGS.

MONDAY, JULY 4.

Conversazione at 7.30 o'clock.

The proceedings will be opened by the Hon. the Lord Provost of Glasgow.

TUESDAY, JULY 5.

Excursion to the Falls of Clyde, in charge of Mr. Geo. Bell.
Excursion to the Trossachs, in charge of Mr. T. N. Armstrong.
Evening meeting at 7.30 o'clock.

WEDNESDAY, JULY 6.

Excursion to Loch Lomond and Loch Long, in charge of Mr. John Stuart.
Excursion to the Yacht Regatta at Largs (by special steamer), in charge of Mr. George Mason.
Evening meeting at 7.30 o'clock.

THURSDAY, JULY 7.

Excursion to Tarbert, Loch Fyne, by steamer "Columbia," in charge of Mr. Wm. Lang, jun.
A group of the members will be photographed at Tarbert by Mr. John Stuart.
No evening meeting.

FRIDAY, JULY 8.

Excursion to Edinburgh. On arrival at Edinburgh the party will be taken in charge by the following Edinburgh friends:—Mr. James Crichton, Mr. William Crooke, and Mr. J. M. Turnbull.
Evening meeting at 7.30 o'clock.

SATURDAY, JULY 9.

A photograph will be taken of a group of the members at 10 o'clock, in Kelvingrove Park, West End.
Meeting of the Committee at 11.30 in the Convention Rooms.

DETAILS OF EXCURSIONS.

TUESDAY, JULY 5.

1.—*To the Falls of Clyde, via Hamilton (in charge of Mr. George Bell).*
—By train, leaving Central Station at 7.55, to Hamilton; thence by coach, driving about thirteen miles, to the Falls. Returning from Hamilton at 5.20; arriving back in Glasgow at six o'clock. Fare, for the trip, about 5s. or 6s. Driving from Hamilton, the party passes through the district called the "Orchard of Scotland." The main points of interest on the drive are Cambusnethan House, Garrison Bridge, Dalserf Village and House, Mauldslee Castle, Milton Lockhart, Ruins of Craignethan Castle, the Tillietudlem of *Old Mortality*. The Falls are three in number—Stonebyers, Cora, and Bonnington; these will fully and pleasantly occupy the day, presenting many fine views to the camera.

2.—*To the Trossachs, via Aberfoyle (in charge of Mr. T. N. Armstrong).*
—By train, leaving Queen-street Station, at 8.10, to Aberfoyle; thence by coach, driving about five miles, to Trossachs and Loch Katrine. Returning from Aberfoyle at 3.45; arriving back in Glasgow at 5.30. Return fare to Aberfoyle, 4s. 6d.; coach extra. The party will have several hours to spend among the magnificent scenery at the Trossachs and Loch Katrine. Those who do not wish to go to the Trossachs may walk from Aberfoyle to Loch Ard, the scenery of which is very fine. Boats may be hired on the Loch, or the excursionists may walk round the Loch side. The whole distance round the Loch is twelve or thirteen miles. Most of the stirring incidents in Scott's *Rob Roy* and *Waverley* are represented as having occurred at Aberfoyle and Loch Ard side: as Bailie Nicol Jarvie's encounter with the Highland gillie, the tree where he was suspended in mid-air, &c. If the party should divide at Aberfoyle, some for the Trossachs and some for Loch Ard, they will reunite at Aberfoyle for return to Glasgow.

WEDNESDAY, JULY 6.

1.—*To Loch Lomond and Loch Long (in charge of Mr. John Stuart).*
—By train, leaving Queen-street Station at eight a.m., to Balloch Pier on Loch Lomond, returning from Arrochar by Loch Long at 2.30, arriving back in Glasgow by Craigendoran to Queen-street Station at seven o'clock. Fare, for the trip, about 7s. The railway to Balloch passes Dumbarton Rock and Castle. The steamer from Balloch sails up Loch Lomond, through the magnificent straits of Balmaha to Luss and Tarbert. Those who wish may leave the steamer at Luss, and walk by the Loch

shore to Tarbet, a distance of seven miles. From Tarbet, on Loch Lomond, the party will walk or drive a mile and a half to Arrocher, on Loch Long. This is a fine road, through a lovely and spacious glen. From the Tarbet end of this glen, there is a fine view of "Ben Lomond," and from the Arrocher end the best view of the "Cobbler." The scenery on these two lochs is as grand as any in the world, being a continuous panorama of wooded hill, grassy slope, mountain peak, and precipice. Coming back, the steamer passes through the delightful shore scenery of the Firth of Clyde.

2.—*Excursion by Special Steamer to witness Yacht Regatta at Largs (in charge of Mr. George Mason).*—By train leaving St. Enoch Station at 8.10 to Prince's Pier, Greenock, embarking there in steamer, and sailing to Largs, returning same way, from Prince's Pier at five o'clock, arriving back in Glasgow at 5.50. Fare for the trip, according to number of party, 7s. to 10s. The conductor of the party will fix time and place for going ashore to dine.

THURSDAY, JULY 7.

Excursion by Steamer "Columba" to Tarbert, Loch Fyne (in charge of Mr. William Lang, jun.).—Steamer leaves Glasgow Bridge at seven o'clock, or parties may take the train leaving St. Enoch Station at eight for Greenock, and join the steamer at Prince's Pier. The steamer goes by Kinn, Dunoon, Inellan, Rothesay, and Kyles of Bute, to Tarbert, returning at 1.20, and arriving back in Glasgow with steamer at seven, or by train from Greenock at six o'clock. This excursion is pretty much a whole day's sail—from Glasgow to Tarbert and back, about one hundred and sixty miles—on a favourite and swift saloon steamer, viewing the charming scenery of the Clyde, and spending two hours at the delightfully interesting fishing village of Tarbert. Fares for the trips, 6s.; or including breakfast, dinner, and tea, 12s. This being the only excursion to-day, it has been suggested that a suitable opportunity might be found at Tarbert for photographing a group of the members; arrangements for this purpose have been made with Mr. John Stuart, who will take a photograph of the group on landing at Tarbert.

FRIDAY, JULY 8.

Excursion to Edinburgh, leaving Queen-street Station at 8.45, returning from Edinburgh at five, and arriving back in Glasgow at 6.15. Return fare, 4s.

Offices of the Convention.—London: 128, Southwark-street, S.E.; Glasgow: The Institute of the Fine Arts, 175, Sauchiehall-street.

Railway Stations.—Caledonian Railway, Central Station, Gordon-street; Glasgow and South-Western Railway, St. Enoch-square; North British, Queen-street. All within five minutes' walk of the Convention Rooms.

The Exhibition will be held within the Institute of the Fine Arts, 175, Sauchiehall-street, and will be open daily.

Public Works and Factories.—Should any of the members wish to visit Public Works or Factories, this can be arranged for by giving notice to the Local Secretary.

A list of members attending the Convention will be posted on the Notice Board in the Office and Meeting Rooms. To facilitate the preparation of this list members are requested, on their arrival in Glasgow, to enter their names and where staying on the list at the Secretary's Office. It is hoped that many of the members will find it convenient to be accompanied by their lady friends to the opening meeting and to all the excursions.

LIST OF HOTELS.

St. Enoch Station Hotel.—Single bedroom and attendance, 2s. 6d. to 4s.; double ditto, 3s. 6d. to 6s.; breakfast, 2s. to 3s.

Central Station Hotel.—Single bedroom and attendance, 2s. 6d. to 5s.; double ditto, 5s. to 7s.; breakfast, 2s. to 3s.

The Bath Hotel, 152, Bath-street.—Single bedroom and attendance, 4s.; double ditto, 7s. to 8s.; breakfast, 1s. 6d. to 3s.

Philp's Cockburn Hotel, 141, Bath-street.—Bedroom and attendance, 2s. 6d. to 3s. 6d.; breakfast, 1s. 6d. to 2s. 6d.

Alexandra Hotel, 148, Bath-street.—Single bedroom and attendance, 2s. 6d. to 3s.; double ditto, 3s. to 4s.; breakfast, 1s. 6d. to 2s. 6d.

Cranston's Waverley Temperance Hotel, 172, Sauchiehall-street.—Single bedroom, one person, 1s. 6d.; two persons, 2s.; double ditto, two persons, 2s. 6d.; more than two persons, 1s. each; boots and service, each person, 1s.; breakfast, 1s. 3d. to 2s.

The two Station Hotels are five minutes' walk of Convention Rooms, all the others are close by the Rooms.

ECHOES FROM THE SOCIETIES.

DURING the past few years, indeed, since the very first introduction of the process, platinotype has been steadily gaining in popular favour, not so much on account of the permanency of its results as by reason of their purely artistic quality. But like every other process, more or less, it undoubtedly requires a particular character of negative to give the best possible results; this condition being complied with, and the subject being one which the matt surface and rich black tone suit,

a fine platinotype will no doubt compare favourably with any style of picture in monochrome that exists. But a platinotype from an unsuitable or inferior negative is one of the sorriest of objects and appears to decided disadvantage when placed side by side with an inferior silver print. What, then, does Mr. T. Sebastian Davis mean by saying, as he did before the Photographic Society, that platinotype and silver prints were found to advantageously set each other off when placed side by side at exhibitions?

As a member of the Council and of the Hanging Committee of the Parent Society for many years, Mr. Davis may be supposed to know something of exhibitions and of the ideas which guide the officials in placing the works on the walls; but if it be a leading principle that the contrast of styles of printing conduces to the natural advantage of the pictures contrasted, it is a wonder, to say the least, that the Royal Academicians have not hitherto discovered the fact and acted on it by mixing up indiscriminately oil and water colours, drawings in black and white, and architectural plans. For instance, how the late Mr. Street's drawings of the New Law Courts, say, and one of Alma-Tadema's classical studies would have "set one another off" if placed side by side! And what a magnificent "foil" one of Perugini's exquisitely humorous studies would make for one of Du Maurier's originals for a cut in *Punch*! Then the idea might be stretched further by the admission of photographs; and the work of Mendelssohn, Lafayette, Bedford, England, and others, placed in contrast with that of Millais, Oulless, B. W. Leader, Keeley, Halleswell, and Peter Graham. Oh, come the happy day!

As a matter of personal recollection, I have at the present moment in my mind's eye an exhibition of some five or six years ago, in which were a couple of series of prints from the same negatives in silver and platinotype respectively. I had seen and admired privately, though separately, prints in both styles, but when they were hung, or rather framed, side by side, the mutual "setting off" was so manifestly to the disadvantage of both that the exhibitor could not fail to be, as he actually was, ashamed of his experiment. And this, be it noted, was with good specimens of each style. Possibly if an inferior silver print have as its foil a still worse platinotype, or *vice versa*, the former may be the gainer, but that can scarcely be called "setting one another off."

There seems to be a misapplication of terms or a confusion of ideas in the suggestion of Mr. F. W. Cox at a meeting of the London and Provincial Photographic Association, where he is reported to have inquired whether the results from paper negatives were not "flatter" than those from glass, proceeding to remark that he had never seen a paper negative that gave "good stereoscopic effect." There does not seem to me to be much connection between flatness in the sense implied in the question and the flatness which signifies absence of relief.

The members of the Association appear to have been exercised in their minds at the same meeting on the subject of a supposed libel upon English photographers, perpetrated by Mr. W. K. Burton in New York. The truth or otherwise of the alleged statement that English photographers were more chary of imparting information than Americans is scarcely worth discussing. The question is, What did the accused say? My theory for the defence is this. We have a dinner, a guest, and the inevitable speech; dinner good, hosts enthusiastic, guest postprandially happy and wishful to be complimentary, speech delivered with the careless effusiveness usual to such occasions. On the other hand, hosts doing honour to the embodiment of a name well known, drink in eagerly what falls from the fount of wisdom, only too glad if it be complimentary to themselves or their great nation. Can it be wondered at—human nature being what it is—that crumbs of comfort should increase, that the minute seed should swell, and burst, and grow, and produce the fruit so unlike its early promise? We have all heard the story of the "three black crows," and therefore, gentlemen of the jury, I appeal to you to return your unanimous verdict for the defendant.

The ways of modern "meetingdom" are essentially unlike those of the past, and the poor old "Parent" is the only relic that I am acquainted with that connects us with a dead barbarism. We are not now tied to the dry and musty technical details of our art-science as we used to be, but a feeling of friendliness and sociability pervades the atmosphere; and even at those meetings where the soothing pipe

and cheering glass are not *en règle*, it is quite permissible to smile "good evening" across the room to a distant friend, or even on specially festive occasions to venture upon a joke, if there be a *bond fide* opening for it.

The readers of THE BRITISH JOURNAL OF PHOTOGRAPHY are acquainted with Mr. A. Cowan as a thoroughly practical man in all he undertakes; those who are in the habit of attending London photographic meetings know him also as the possessor of a fund of humour, upon which he is ready to draw at a moment's notice when required. But it is really cruel to report his sallies in the incomplete manner adopted by the prosaic reporter of the London and Provincial Photographic Association. Robbed of the suggestive inflection of voice, and perhaps the slight droop of one eyelid, the accompanying volley of laugh and chaff, a reported joke falls flat indeed, even when made the most of. "The business of a procession is to process," Mr. Cowan is reported to have said; but I for one do not believe he said anything of the sort, for he knows as well as anybody else that its duty is to *proceed*, while every one must have recently experienced the fact that the general result is to make itself a nuisance. The reporter is more successful in his second attempt, when, in reply to Mr. Henderson's statement that he had failed in his attempt to photograph Her Majesty with a Suter lens, Mr. Cowan surmised that "the lens did not suit her."

As an example of a truly fruitless discussion, I cannot help referring to a recent meeting of the Bury Photographic and Arts Club; not that the subject was a useless or unsuitable one to bring before the society, but simply because of the unsatisfactory character of the data. A print which had faded nearly out was alleged to have "been thoroughly washed and mounted with a reliable mountant," and, moreover, to have been "kept in a dry place." It would, under the circumstances, have been difficult to find any other cause for the result, and therefore the *mount* was made the scapegoat. But the questions arise in, What is "thorough washing?" What is a "reliable mountant?" and, What is a "dry place?" and, further, Who guarantees the conditions in this particular instance? I am reminded of the examination question, "What would be the result if an irresistible force were brought to bear on an immovable object?"

Mr. Marsh's demonstration of emulsion making before the North Surrey Photographic Society was, no doubt, most interesting, especially as only "a few ordinary household utensils" were brought to bear on an "imaginary emulsion." Emulsion making is the easiest thing in the world in imagination or theory—so for that matter is rifle shooting. But to make an emulsion that will work when made, or to put on a "highest possible" at 800 yards, is far more difficult in actual practice than when working on an "imaginary" emulsion or a "dummy" target. But the game is not finished when the emulsion is made. The plates have to be coated, levelled, and dried, and this part of the process requires quite as much care—of another kind, perhaps—as the emulsion making, and will prove to be far more troublesome and inconvenient to the large majority of amateurs.

By-the-by, what does Mr. Marsh mean by describing "the making of an emulsion by the ammonio-nitrate method, *by which the trouble of washing is avoided?*" The italics are mine. Is this another instance of incorrect reporting? What, again, was the size of the negatives exhibited, containing only "about a grain of silver in the film of each?" And does this refer to the fixed or unfixed image? If the former, how does Mr. Marsh compute the quantity of silver?

Here is an idea from Philadelphia. Postal cards are sold ready sensitised for the production of ferro-prussiate or "blue" prints. Such cards might prove useful for advertising purposes in this country for disseminating designs in a cheap manner. Nothing is allowed to be attached or pasted to a post card, but there is no law to prevent a photograph being printed instead of stuck on to the card.

MONITOR.

THE MANCHESTER EXHIBITION.

III.

An argentic enlargement, *Portrait of a Lady*, by S. Fry & Co., looks like a fine engraving. No greater praise could be bestowed upon it; but this is a characteristic of a large number of photographs in this Exhibition.

Why does Robert Faulkner designate so many of his works as "portraits on red opal?" This is incorrect: they are on *white* opal, although the material of the pictures is red pigment. If this latitude in nomenclature be permissible, why not speak of red paper or black opal? But "a rose by any other name will smell as sweet," and the considerable number of Faulkner's exhibits sustain his reputation. Abel Lewis, L. Berry, and William Crooke, are extensive exhibitors of work mainly of a high class; but a portrait by the last-mentioned in "red opal" is not equal to his platinotypes, which are much above the average. J. H. Hogg, in addition to some good platinotypes, goes in also for red portraits in Faulkner's style. Wonderfully good is a bromide enlargement of a girl and dog, by J. Ingham, although in this and in quite a number of cases by other artists we are left in doubt as to whether the enlargement was made by the exhibitor or not.

W. J. Byne contributes a collection of portraits taken in his best style. The well-known names of Vernon Heath and William Bedford are among the exhibitors, their works consisting of landscapes, those of Mr. Bedford being scenes in North Wales.

We have here an opportunity of comparing the ceramic enamels of Count Ostoróg (Walery) and A. L. Henderson and ascertaining their relative merits, as their exhibits are hanging side by side. Until we saw it on Walery's frame, we were unaware that he worked by a patent process. If it is one that has been patented in this country, we have quite overlooked it, nor have we yet been able to find it in our Patent Office archives.

Hanging in the portion of the Exhibition among the outsiders, are some works by local artists, among whom are Warwick Brookes, who has a large collection of portraits of admirable quality, and A. Brothers, whose picture, *Resignation*, is a very fine carbon photograph.

Quite imposing in their grand repose are the enlarged photographs of some of the wild animals in the London Zoological Gardens by Dixon & Son; and imposing, too, is a fine bromide enlargement of the west front of Rouen Cathedral by Rev. H. J. Palmer, who, however, exhibits several other works of equal merit.

We are glad to perceive on the walls, and effectively displayed, Mayland's grand picture, *There is Sorrow on the Sea*. We find also a number of highly attractive landscapes and other scenes by Matthew Whiting, with a frame of interiors by Bedford Lemere. The contributions of the members of the Manchester Societies, as might be expected, are both numerous and of excellent quality in the main. But our space at present necessitates deferring a notice of them till next week.

COLOURING AS APPLIED TO PHOTOGRAPHY.

WE are now in an age when hopeful minds and even speculative companies are straining every nerve to discover an easy method of arriving at a coloured photograph. Those artists who have for years given their best services to help the photographer in this branch, however, may peacefully carry on their pursuits unworried by the blatant cries of a few interested people, who declare they have mastered the secrets of nature so far as to be able to produce a photograph in natural colours. There have been many such wild reports sent abroad, but whenever any one wanted a photograph coloured the photographer has always had to call in the aid of an artist for the purpose. He found photography, pure and simple, incompetent to help him through his trouble.

It is now more than a hundred years ago since photography showed first signs of life. I believe it was about 1777 that the first germ of photography was discovered by Scheele. I have not the least doubt, too, that he then never thought that photography would hold the position it has to-day. It was fully fifty years after this date that this same germ, in the hands of Talbot, Daguerre, and Niépce, gave signs of life. Under their careful and skilful treatment photography proper may be said to have made its *début*. The advancing strides of photography since those days have been not only rapid but amazing, until to-day it assumes the position almost of a distinct art. Photography might not inaptly be compared to a mighty tree with numerous and healthy outspreading branches. It is to one of these branches that our attention is being directed.

Notwithstanding the supposed existence of "photography in natural

colours," I will venture upon saying that up to the present, at least, photography has only furnished us with the image of an object with its light and shade, but *without* its natural colouring. There is little doubt, too, in the minds of men who *ought* to know, that this state of affairs is very likely to last for a considerable time in the future. Whether any method or system will ever be discovered by which the natural and distinctive colours of the various objects will be reproduced *by chemical means solely*, may be safely left for the dim future to determine. Up to the present time painting has had to supply this effect.

Form must necessarily be the basis of all art, but in many cases colour is almost as necessary if a true portrait be the object in view. There is no class of painting which exercises the mind of an intelligent artist more than does portraiture. There are very few now (but there are a few even now) who believe in the unerring truthfulness of a photograph to reproduce nature as nature really is. As I say, there are a few who still hold the opinion that a really *good* photograph is one of, if not absolutely, the greatest triumphs of art. The believers in this theory should not read further, but to those who do not believe in it the following may prove interesting, and perhaps instructive.
